During the second five-year plan the industrial output increased by 66 percent, rising to four times the prewar level (1937). The national income increased by a factor of 2.5 between 1948 and 1960. The socialist sector now owned 87.4 percent of the farmland, and the organization of farmers into cooperatives was virtually completed. Nevertheless, in terms of the growth of production, agriculture lagged behind industry. The successes of socialist construction quickly raised the living standard of the people. A national conference of the Communist Party, held on July 5–7, 1960, confirmed the victory of socialist production relations in the country. Several days later, on July 11, the National Assembly adopted a new constitution under which the country was renamed the Czechoslovak Socialist Republic (CSSR). The constitution proclaimed the CSSR a socialist state based on a firm alliance, headed by the working class, of the peasantry, the working class, and the intelligentsia.

Economic development slowed during the third five-year plan (1961–65), chiefly owing to an exhaustion of the means of production expansion, but also because of shortcomings in the management of the national economy and a weakening of centralized control. The Twelfth Congress of the Communist Party (December 1962) stated that the objectives of further economic development were to improve planning, correct the imbalance between the development levels of industry and agriculture, and establish an equilibrium between output and consumption.

In the years of socialist construction the working people of Czechoslovakia, led by the Communist Party, achieved notable successes in economic, scientific, and cultural development and in raising the living standard of the population. Nevertheless, the road to socialism was strewn with obstacles and difficulties, and some mistakes were made. The level of development of society and the degree of its moral and political unity were overestimated; Marxist-Leninist principles were inconsistently applied in the life of the party and society; and a subjectivist approach was taken to the solution of several important problems. Not enough attention was given to the ideological work of the party. The struggle against bourgeois ideology and petit bourgeois views was relaxed, permitting the spread of revisionist trends in the party. At the same time, the pressure of bourgeois propaganda intensified, and foreign imperialist forces stepped up their subversive activity. The party's Thirteenth Congress (May–June 1966) proposed ways to overcome the difficulties. However, neither party nor government leaders took the necessary steps to implement the decisions of the congress and to eliminate shortcomings and errors, a lapse that led to a crisis in the party and in society.

The January 1968 Plenum of the party's Central Committee set three basic tasks: eliminating from the activity of the party or its leadership anything that hindered the further development of the socialist society, strengthening the alliance between Czechs and Slovaks through a consistent implementation of the Marxist-Leninist nationality policy, and solving pressing economic problems. But right-wing opportunists gained the upper hand in the party leadership elected at the plenum; A. Dubček was elected first secretary of the Central Committee. The new leadership was incapable of carrying out the tasks set by the Thirteenth Congress and the January Plenum, and its actions contributed to a large-scale offensive by right-opportunist and antisocialist forces against the party's policy and the socialist system. Under cover of demagogic slogans calling for the "democratization" of society and the creation of a "new model" of socialism, the right-opportunist and antisocialist forces launched virulent attacks on socialism, seeking to abolish the leading role of the working class and its vanguard, the Communist Party, to dismantle the agencies of socialist power, and to break Czechoslovakia's alliance with the USSR and the other socialist countries. Supported by Western imperialist circles, the newly formed political coalition of right-opportunist and antisocialist forces began making extensive preparations for a counterrevolutionary coup aimed at restoring the bourgeois system.

By August 1968 a critical counterrevolutionary situation had developed in Czechoslovakia, and the country was on the brink of civil war. Under these circumstances, thousands of Communists and nonparty citizens, many members of the Central Committees of the Czechoslovak and Slovak Communist Parties, members of the cabinet, and deputies to the National Assembly, realizing that the imminent counterrevolution could no longer be averted with internal forces, asked the governments of the socialist countries and the leading bodies of the fraternal parties to extend international aid to the Czechoslovak people in the defense of socialism. Such assistance was rendered in August 1968 by the allied socialist countries: the USSR, the People's Republic of Bulgaria, the Hungarian People's Republic, the German Democratic Republic, and the Polish People's Republic. With international support, the Marxist-Leninist forces within the Communist Party of Czechoslovakia assailed the antisocialist elements, opportunists, and revisionists and mobilized the working class and all the working people for the defense of the socialist achievements.

A turnaround in both the party and the country occurred after the April 1969 Plenum of the party's Central Committee, which elected a new party leadership headed by G. Husák. The May 1969 Plenum of the Central Committee adopted a program of consolidation designed to deal with the consequences of the crisis. Work began on rallying the party around the principles of Marxism-Leninism and on purging it of opportunists and careerists through an exchange of party membership cards, completed in 1970. Measures were taken to strengthen government and administrative bodies, to reinforce state planning and economic management, to stabilize the economy, and to regain the trust of and reestablish fraternal ties with the CPSU and the communist parties of the other socialist countries. It was thus possible to normalize the situation in the country and strengthen the party's authority, enabling the working people of Czechoslovakia to continue their constructive labor.

On May 6, 1970, the CSSR and the Soviet Union signed a new treaty of friendship, cooperation, and mutual aid that still further expanded and deepened the fraternal relations between the two countries. The December 1970 Plenum of the party's Central Committee adopted the document Lessons Drawn From the Crisis Development in the Party and Society After the Thirteenth Congress of the Communist Party of Czechoslovakia, giving an

in-depth Marxist-Leninist analysis of the recent events and showing how the threat of a counterrevolutionary coup had arisen and how it had been eliminated. In particular, the document noted that the international aid of the fraternal socialist countries had been timely, necessary, and the only correct solution.

In assessing this complex period in the history of the party and the country, the Fourteenth Congress (May 1971) affirmed that the task of restoring the Communist Party of Czechoslovakia as a Marxist-Leninist party had been carried out and that the party was now able to resume its historical role as the leading force in society. The congress also stated that the socialist principles of economic, scientific, and cultural development had been reestablished. The Fourteenth Congress has been called the congress of victory over the enemies of socialism in Czechoslovakia and the congress of the triumph of socialism and proletarian internationalism. But the congress also pointed out that opportunism and revisionism continued to present the main danger and called for an uncomprising struggle against them. The congress ratified the directives for the fifth five-year economic plan (1971–75), which gave priority to raising the efficiency of the national economy through a maximum utilization of intensive growth factors and to meeting the growing needs of the people. The decisions of the congress opened the way for the further comprehensive building of a socialist society in Czechoslovakia.

In the national and local elections held in November 1971 the voter turnout was 99.45 percent. National Front candidates to the House of the People polled 99.81 percent, and those to the House of Nations received 99.77 percent of the votes cast. Husák, general secretary of the Central Committee of the Communist Party and chairman of the Central Committee of the National Front, was elected president of the CSSR in May 1975. The Fifteenth Congress of the Communist Party (April 1976) was an important event in the life of Czechoslovakia. Summing up the results of socialist construction, the congress noted that from the standpoint of economic and social development the preceding five years had been one of the most successful periods in the history of socialist construction in Czechoslovakia. The congress set a task of programmatic significance—the building of a fully developed socialist society in Czechoslovakia—and established the main economic and social objectives for the next five years. It emphasized the need to develop the state and improve the political system, to invigorate party work, and to strengthen the leading role of the party. The congress demonstrated the fidelity of the Czechoslovak Communists and working people to the ideas of proletarian internationalism.

Czechoslovakia has concluded treaties of friendship and mutual assistance with most of the socialist countries, including Poland (1947, 1967), Bulgaria (1948, 1968), Rumania (1948, 1968), Hungary (1949, 1968), the Mongolian People's Republic (1957, 1973), the People's Republic of China (1957), and the German Democratic Republic (1967, 1977). It has been a member of the Warsaw Treaty Organization since 1955. A founding member of COMECON (Council for Mutual Economic Assistance), Czechoslovakia is carrying out the organization's joint program of socialist economic integration. The Soviet Union, Czechoslovakia's principal trading partner, is also rendering technical assistance in the construction of several industrial enterprises, nuclear power plants, and the Prague subway. Czechoslovakia in turn is helping to build many industrial enterprises in the USSR. The coordination of national economic plans is an important factor in the economic cooperation between the two countries, which are also rapidly expanding their scientific and technical cooperation and cultural ties.

Czechoslovakia's strength as a socialist state has enhanced its prestige in the international arena. A founding member of the UN, Czechoslovakia has cosponsored many proposals of the socialist countries aimed at relaxing international tension and strengthening peace. Having contributed to the preparation and successful conclusion of the Conference on Security and Cooperation in Europe (1975), Czechoslovakia is working with the other socialist countries to implement the conference's decisions.

Czechoslovakia's relations with the capitalist countries rest on the principles of peaceful coexistence and mutually advantageous cooperation. In 1973 it concluded a treaty establishing diplomatic relations with the Federal Republic of Germany. The treaty reaffirmed the inviolability of the border between the two countries, which pledged to respect each other's territorial integrity and to refrain from making territorial claims on each other. The parties declared the Munich Pact of 1938 to be null and void. The signing of the treaty contributed to an improvement of the political climate in Europe.

The CSSR maintains political, trade, and cultural relations with many Asian, African, and Latin American countries and renders them economic, scientific, and technical aid. A number of enterprises in India, Syria, Iraq, and other countries have been completed or are being built with its technical assistance. As of December 1979, Czechoslovakia maintained diplomatic relations with 124 countries and traded with almost as many nations. It is a member of more than 54 major international organizations.

Political parties, the National Front, trade unions, and other social organizations

Political parties. The Communist Party of Czechoslovakia (CPC; Komunistická Strana Československa), founded in 1921, had 1,525,000 members and candidate members as of Jan. 1, 1980. The Communist Party of Slovakia (CPS; Komunistická Strana Slovenska) is the regional organization of the CPC in Slovakia. The Czechoslovak Socialist Party (CSP; Československá Strana Socialistická) was founded in 1948 by some members of the Czech National Socialist Party, which had existed since 1897 and which had been called the Czechoslovak Socialist Party from 1918 to 1926. The CSP draws its main support from several strata of the population that formerly belonged to the urban middle and petite bourgeoisie and the intelligentsia, but it also attracts a small segment of the workers and peasants. It operates only in the Czech lands. The Czechoslovak People's Party (CPP: Československá Strana Lidová) was founded in February 1948 after the reorganization of a bourgeois party of the same name that had existed since 1918. It brings together part of the peasantry, several former petit bourgeois strata, some artisans and members of the intelligentsia, and a negligible number of workers. Most of the members of the CPP, which operates only in the Czech lands, are practicing Christians.

The Slovak Reconstruction Party (Strana Slovenskej Obrody) was founded in February 1948 by the more progressive elements in the Democratic Party, which broke up during the February events of 1948. It unites a small part of the urban and rural working people of Slovakia. The Slovak Freedom Party (Slovenská Strana Slobody), founded in 1946 by secessionists from the Democratic Party, is supported by an insignificant part of the former Slovak petite bourgeoisie and by a small number of office employees and members of the intelligentsia, chiefly Roman Catholics.

All the non-Communist parties recognize the CPC's leading role in society and support the program of building socialism.

National Front. Founded in 1945 on the initiative of the CPC, the National Front (Národní Fronta) is the political expression of the CPC-led class alliance of the urban and rural working people. It embraces all the country's political parties and the main social organizations.

Trade unions and other social organizations. The country's occupational and social organizations function in accordance with the country's federal structure, that is, Czech and Slovak organizations are administered on a federal basis. The Revolutionary Trade Union Movement, founded in April 1946, had about 7 million members in 1980. It is a member of the World Federation of Trade Unions.

The Socialist Union of Youth, founded in 1970 and with 2.3 million members in 1980, carries on the revolutionary traditions of the Czechoslovak Komsomol, founded in 1921, and the Czechoslovak Union of Youth, established in 1949. The Czechoslovak-Soviet Friendship Alliance, founded in 1948, had about 2.5 million members in 1980. The Czechoslovak Women's Union, formed in 1974 from women's organizations founded in 1967, had a membership of 800,000 in 1980. S. I. Kolesnikov

Economic geography

General characteristics. The CSSR is an advanced industrial country with an intensive agriculture and a high living standard and culture. It accounts for more than 1.5 percent of the world's industrial output and for about 5 percent of the industrial output of the COMECON countries. In terms of volume of industrial output the CSSR holds 11th or 12th place in the world. In 1976 industry provided 68 percent of the national income, construction 12.9 percent, agriculture and forestry 7.2 percent, transportation and communications 2.7 percent, and commerce, food services, and other sectors 9.2 percent. About one-third of the national income is derived from foreign trade. In 1976 the socialist sector accounted for 99.6 percent of the national income, for 99 percent of the production fixed assets, for 100 percent of the gross industrial output, and for 96.8 percent of the gross agricultural output.

The Czechoslovak economy has passed through several stages of socialist construction and radical social and economic change (*see above*: Historical survey). These stages are reflected in a series of economic development plans, the two-year plan of 1947–48 and the five-year plans of 1949–53, 1956–60, 1961–65, 1966–70, and 1971–75. In accordance with the decisions of the Communist Party congresses, economic policy was aimed at modernizing industry and creating a large-scale socialist agriculture. Precedence was given to the development of heavy industry. The industrial output of Czechoslovakia, a highly industrialized country even before the war, grew almost tenfold between 1949 and 1976, with the output of machinery increasing 23 times and of chemical products 27 times. These quantitative changes were accompanied by qualitative changes in the structure of industry. By 1976 capital goods accounted for two-thirds and con-

sumer goods for one-third of the total value of the industrial output. The number of workers employed in machine building and metalworking doubled between 1937 and 1975. Meanwhile, agriculture shifted from small-scale production to large-scale modern production carried out by cooperatives. Productivity increased by more than 50 percent per unit of farmland, and farm labor productivity rose by a factor of 4.4. The economy as a whole developed rapidly: between 1949 and 1976 the gross social product increased sixfold and the national income more than fivefold.

In the years of people's rule the regional inequalities in living standard inherited from capitalism have been eliminated, and full employment has been achieved. The differences between working conditions in industry and agriculture are being erased gradually. Economically backward regions no longer exist; the formerly agricultural regions have been industrialized; and the historical disparity between the western and eastern parts of the country has been essentially eliminated. Formerly an agricultural area, Slovakia has become an industrial and agricultural land, its share in the country's industrial output rising to 26 percent, compared to 7 percent in 1937. The five-year national economic plan for 1971–75 prescribed measures aimed at integrating the development of the country as a whole with the proportional development of the economies of the republics.

Czechoslovakia's economy has entered the period of building a fully developed socialist society. The sixth five-year plan (1976–80) calls for raising production efficiency and accelerating scientific and technological progress as the basis for the dynamic development of the whole national economy. An important factor in the overall rise in economic efficiency is Czechoslovakia's participation in the international socialist division of labor. In line with the Comprehensive Economic Integration Program of the COMECON countries, specialization and cooperation in both production and scientific and technical research are developing rapidly. Within COMECON the CSSR specializes in various branches of machine building, including the manufacture of machine tools, equipment for nuclear power plants, and textile machinery.

Industry. Postwar industrial development has been marked by a rapid growth rate (averaging 6.7 percent a year between 1966 and 1976) and changes in the branch and regional structure of industry (see Table 2). The tempo of growth has been greatest in the chemical and machine-building industries. Other expanding industries have included electronics, electrical and vacuum engineering, precision mechanics, and computer technology. Radical changes have taken place in light industry and in the food industry, which in the past were dispersed and fragmented, with only 3 percent of the enterprises employing more than 20 people. Like the newer branches of industry, they are now highly concentrated and specialized. About 50 percent of the country's industrial labor force is employed in enterprises with more than 1,000 workers, compared to 18 percent before World War II. Large economic associations, called economic production units, were established in the 1970's; there are about 100 of them in industry and construction. (See Table 3 for the output of the principal industrial goods.)

Industrial production, notably machine building, is now relatively evenly distributed throughout the country, largely owing to the construction of large industrial facilities in eastern Czechoslovakia, as well as in some parts of Bohemia and Moravia. Of the roughly 2,000 industrial enterprises and separate installations that were built in the CSSR between 1945 and 1970, 181 employ more than 1,000 workers. The CSSR holds a leading place among the COMECON countries and a prominent place in the world in the per capita output of such important industrial products as pig iron (635 kg; figures for 1976 unless otherwise indicated), steel (985 kg), rolled metal (697 kg), metalcutting machine tools (21.3 units per 10,000 population), passenger cars and trucks (145.1 units per 10,000 population), paper (all types, 55.7 kg), cotton fabrics (35.2 m), wool fabrics (5.7 m), footwear (7.9 pairs), and sugar (56.9 kg in 1975).

MINING AND POWER ENGINEERING. The CSSR has limited fuel, energy, and mineral resources. Its substantial coal reserves account for more than 90 percent of its fuel and energy resources and are the main source of electric power. Imported oil and natural gas play a major role in the production of energy; in 1976 imports, chiefly from the USSR, amounted to 17.1 million tons of crude oil, 4.5 billion cu m of gas, and 4.6 billion kilowatt-hours of electric power. In 1975 the structure of the fuel and energy balance was as follows: solid fuel, 66 percent; oil, 24.7 percent; fuel gas, 5.5 percent; nuclear energy, 8.0 percent; and water and other types of energy, 3.8 percent.

More than 85 percent of the hard coal is mined in the Ostrava-Karviná Basin and about 8 percent in the Kladno region near Prague. Most of the hard coal is used for coking; of the 11 million tons of coke produced in 1976, 2.1 million tons were exported. There has been a rapid growth in the output of brown coal, mined chiefly in the western part of the country—in the North Bohemian Brown Coal Basin (72 percent) and in the Sokolov Basin (23 percent). Almost 90 percent of the coal is mined by open-cut methods. Of high quality, brown coal is used mainly to fuel thermal electric power plants and to produce gas (8 billion cu m in 1976). The production of oil and natural gas is insignificant: 131,000 tons and 982 million cu m in 1976.

Most of the country's electric power is produced by thermal electric power plants using chiefly brown coal but also hard coal. The installed capacity of the electric power plants was 14.6 gigawatts in 1976, of which 1.8 gigawatts were generated by hydroelectric power plants. About 40 percent of the electricity is produced in the North Bohemian Brown Coal Basin and about 15 percent in the Ostrava-Karviná Hard Coal Basin. The largest power plants, whose capacity ranges from 800 to 1,300 megawatts, are located at Tušimice, Počerady, Prunéřov, Mělník, Detmarovice, and Vojany. The first unit, with a capacity of 500 megawatts, is being installed at the Mělník-3 Thermal Electric Power Plant. Hydroelectric power plants have been built on the Vltava and Váh rivers. The largest, the Orlík Hydroelectric Power Plant on the Vltava, has a capacity of 420 megawatts. The

Table 2. Branch structure of industry

	Percentage of industrial labor force			*Percentage of gross industrial output*
	1930	*1960*	*1976*	*1976*
Fuel and energy	10.1	9.9	8	9.1
Metallurgy	21	7.4	7.5	10.9

water resources of the Danube are also being harnessed. The country's first nuclear power plant, with a capacity of 150 megawatts, has been put into operation at Jaslovské Bohunice; a second nuclear power plant is being built nearby. The Dukovaní Nuclear Power Plant is under construction in Moravia (1978). The country's unified power grid is connected with the Mir System.

The CSSR produces nuclear raw materials, magnesite, antimony, kaolin, iron ore (1.9 million tons in 1976), and small quantities of copper and lead and zinc ores.

MANUFACTURING. The well-developed ferrous metallurgy industry uses local coal and chiefly imported iron ore (85 percent), most of it supplied by the USSR. In the years of people's rule old plants in Ostrava, Třinec, and Kladno have been modernized, and two large metallurgical works have been built, the K. Gottwald Combine in Ostrava and the Eastern Slovakia Combine in Košice. Most of the ferrous metallurgy works are concentrated in the Ostrava-Karviná region, which produces more than 60 percent of the pig iron and about 60 percent of the steel. A large proportion of the high-grade steel comes from plants in Kladno and Plzeň, as well as from Central Slovakia. Ferroalloys are produced in North Slovakia. Part of the ferrous metallurgy output is exported; in 1976 exports included 2.7 million tons of rolled metal and 500,000 tons of pipe.

The nonferrous metallurgy industry lacks sufficient local raw-material resources. In 1975 the CSSR produced 18,400 tons of copper, 22,000 tons of lead, and 43,300 tons of aluminum. The aluminum plant built at Žiar and Hronom in the early 1950's uses mainly Hungarian bauxite. A cobalt and nickel plant has been built in Sered'. Much of the need for nonferrous metals is met by imports.

Machine building and metalworking, the leading branch of industry, are oriented toward small-lot and medium-lot production with a wide assortment of goods. The years of people's rule have seen substantial changes in the branch structure of machine building. The output of equipment for the power, rolled-metal, chemical, and textile industries, of vehicles, and of metalcutting machine tools has increased considerably, and many modern branches have emerged, such as the manufacture of equipment for nuclear power plants and for the electronics industry. The manufacture of vehicles holds an important place in the structure of machine building, accounting for about one-third of the value of the industry's output. Plants manufacturing diesel and electric locomotives, railroad cars, streetcars, motor vehicles, and motorcycles are concentrated at Prague, Plzeň, Martin, and Mladá Boleslav. A shipbuilding industry has been established in Komárno and a tractor industry in Brno. Machinery for the power industry accounts for about one-fifth of the output of machine building. Equipment for thermal electric and hydroelectric power plants and electrical goods are produced in Prague, Brno, Plzeň, Bratislava, and Pardubice. Machine-tool enterprises are found in Prague, Plzeň, Brno, Kuřim, and Gottwaldov; the CSSR is the second-largest producer of metalcutting machine tools among the COMECON countries, after the USSR.

About half of the machine-building output comes from the Prague, Brno, and Plzeň industrial conurbations. The country's main center of machine building is Prague, noted for the production of transport, heavy, and electrical machinery. The city's largest machine-building enterprise, the ČKD-Prague, produces heavy and transport machinery. The automotive industry is well established. The country's three main plants—the Tatra Plant in Kopřivnice, the Škoda Plant in Mladá Boleslav, and the plant in Prague (now the Gottwald Plant)—began producing passenger cars and trucks as early as the turn of the century. Another major engineering center, Brno, is the site of several large plants specializing in the manufacture of heavy power engineering equipment, metalcutting machine tools, and tractors. One of the country's largest machine-building enterprises, the V. I. Lenin Works (formerly Škoda) in Plzeň, has several production divisions turning out electrical, power engineering, metallurgical, and transport equipment.

The rapidly expanding chemical industry is becoming one of the country's main branches of industry. Old plants producing sulfuric acid, soda ash, and other inorganic chemical products are being modernized, and industrial organic synthesis is developing rapidly on the basis of Soviet oil and natural gas. The organic-synthesis industry produces plastics and synthetic resins (581,000 tons in 1976), chemical fibers, and synthetic rubber. Large amounts of nitrogen and phosphate fertilizer are also produced. Chemical enterprises along the Middle and Lower Labe account for about half of the industry's output. Záluží near Most is the site of one of the country's largest chemical combines, the Czechoslovak-Soviet Friendship Combine, which uses oil as the starting material. The country's largest oil refinery, Slovnaft in Bratislava, has an annual capacity of about 9 million tons and produces dozens of different chemical products. Cooperation with the German Democratic Republic (GDR) is developing under the "olefin program"; an ethylene pipeline links Záluží with Böhlen in the GDR.

The output of construction materials is increasing. To supplement the output of the old cement enterprises in Central Bohemia and North Moravia, new plants have been built in Central and South Moravia, East Bohemia, and Central and East Slovakia. Part of the rapidly expanding output of magnesite refractory materials and ceramic products is earmarked for export.

Table 4. Sown area and yield of chief crops

	Sown (hectares)			Harvest (tons)		
	1934–38[1]	1961–65[1]	1976	1934–38[1]	1961–65[1]	1976
Wheat	882,000	739,000	1,278,000	1,513,000	1,779,000	4,807,000
Rye	983,000	429,000	186,000	1,577,000	897,000	561,000
Barley	653,000	687,000	857,000	1,109,000	1,556,000	2,901,000
Oats	748,000	418,000	198,000	1,212,000	792,000	379,000
Corn	105,000	200,000	204,000	225,000	474,000	514,000
Sugar beets	166,000	235,000	214,000	4,664,000	6,277,000	5,248,000
Potatoes	715,000	492,000	240,000	9,635,000	5,635,000	4,214,000

[1]Annual average

The glass industry, one of the oldest traditional branches, uses local raw materials. Bohemian glass, crystal, and glass jewelry continue to be highly esteemed, and the output of industrial glass is growing. Most of the glass factories are located in North and West Bohemia, where the main centers are Jablonec and Karlovy Vary. Another popular product is ceramic ware, notably porcelain, made from high-quality local kaolin. Most of the porcelain and other ceramic products are manufactured in West Bohemia, chiefly at Karlovy Vary and Horní Bříza, where kaolin is extracted and processed.

The wood-products industry uses mainly domestic raw materials. Enterprises of the lumber and pulp and paper industry are generally found in the forested mountain regions of North and South Bohemia and Central and East Slovakia. The furniture industry is highly developed, and paper, furniture, pencils, and other products are exported to many countries.

The highly diversified textile industry, the leading branch of light industry, has been completely modernized in the years of socialist construction, when large enterprises equipped with up-to-date machinery were built. Although the number of workers employed in the textile industry has declined considerably, the volume of output is steadily increasing. The cotton industry is dispersed throughout North Bohemia, and the woollen industry tends to be confined to large cities, such as Brno and Liberec. The output of rayon fabrics, made chiefly from domestic chemical fibers, is growing. The linen industry, situated in northeastern Bohemia and using both domestic and imported flax, is noted for the high quality of its products. The flourishing clothing industry exports part of its output. The leather and footwear industry also produces both for the national market and for export. Its shoes and leather accessories are well known abroad. Czechoslovakia ranks first in the world in the per capita output of footwear. More than half of the footwear is produced by the Svit Factory (formerly Batá) in Gottwaldov.

Table 5. Livestock and poultry[1]

	1960	1970	1976[2]
Cattle	4,387,000	4,288,000	4,654,000
cows	2,047,000	1,881,000	1,898,000
Hogs	5,962,000	5,530,000	6,820,000
Sheep	646,000	981,000	797,000
Horses	330,000	131,000	57,000
Poultry	28,200,000	39,200,000	44,100,000

[1]End of year [2]67 head of cattle, 98 hogs, and 11.4 sheep per 100 hectares of farmland

The food and condiment industry uses mainly local raw materials and essentially satisfies the country's needs. Sugar refining and brewing have long been important branches. Czechoslovakia is one of the world's major producers of beet sugar, exporting from 25 to 30 percent of its output. Most of the sugar refineries are located in the farming areas along the Labe River, in the Moravian valleys, and on the Danubian Plain. The world famous Bohemian beer is brewed at Plzeň, Prague, and České Budějovice.

Agriculture. In 1975 the socialist sector controlled more than 94 percent of the farmland. In 1976 the country's 213 state farms averaged 4,600 hectares (ha) of plowland, and its more than 2,000 agricultural production cooperatives of all types averaged 1,600 ha of plowland. State agricultural enterprises manage 2.1 million ha of farmland and agricultural production cooperatives, 4.3 million ha. Various types of agricultural-industrial complexes have been set up with a view to mechanizing agriculture. Although the agricultural labor force has declined considerably, socialist changes, capital investments (a tenfold increase in the supply of means of production), and a rise in labor productivity have resulted in a substantial growth in the gross agricultural output, which in 1976 exceeded the prewar level by 36 percent. Most of the growth has taken place in animal husbandry, whose output increased by 66 percent, while the crop farming output rose by 9 percent. In 1976 the gross agricultural output was 4.3 times greater per worker and 1.5 times greater per ha of farmland than the prewar output.

Czechoslovak agriculture is highly intensive. The country ranks fifth or sixth in Europe in the per capita value of agricultural output, and it holds seventh or eighth place in the value of output per ha of agricultural land. Czechoslovakia also ranks high in the number of tractors per unit of farmland (one tractor [converted to 15 horsepower] per 10 ha of cultivated land) and in the application of fertilizers (242 kg in net weight per ha of plowland in 1976). The country produces almost enough bread grain and animal products to satisfy domestic consumption, and measures are being taken to make the country more self-sufficient in other types of foodstuffs. In general, the country's agriculture satisfies about 85 percent of the domestic demand for foodstuffs. Czechoslovakia imports feed grain, vegetables, fruit, and some agricultural raw materials, chiefly cotton and wool, and it exports sugar, hops, malt, and beer.

The postwar years have seen structural changes in agriculture; the share of animal husbandry and crop farming in the gross agricultural output has shifted from 45.9 percent and 54.1 percent, respectively, in 1936 to 57.1 percent and 42.9 percent in 1976. Of the 7 million ha of farmland in 1976, plowlands occupied 4.9 million ha, perennial plantings 360,000 ha (including vineyards 43,000 ha), and natural meadows and pastures 1.7 million ha. Forests covered 35 percent of the country, or 4.5 million ha.

CROP FARMING. The structure of the sown area has changed in favor of expanded plantings of fodder and industrial crops. In 1976 grain and pulses covered 57.6 percent of the sown area (compared to 63.2 percent, the annual average for the 1934–38 period); industrial crops, 6.9 percent (4.2 percent); potatoes and vegetables, 6.1 percent (13.6 percent); and fodder crops, 29.1 percent (19 percent). A growth in grain yield (the current yield of almost 40 quintals per ha far exceeds the European average) has raised harvests considerably above the prewar level. Table 4 shows the sown area and harvest of the principal crops.

Wheat is grown mainly along the Labe, in the Danubian Plain, in the valleys of Moravia, and in the Tisza Lowland. Barley is also grown in these regions, especially industrial strains used for making malt. Corn is grown mainly in southern Slovakia. The most important industrial crop is sugar beets, grown for centuries along the Labe and in the valleys of Moravia and now raised in increasingly large quantities on the Danubian Plain. Large areas are planted to oil-bearing crops, chiefly rape, and to fiber crops, predominantly flax. Potatoes are grown in the hilly regions, principally in the Bohemian-Moravian Uplands. The grape harvest amounted to 209,000 tons in 1976. An important perennial crop is hops, for which the country is famous. Orchards are found throughout the country.

ANIMAL HUSBANDRY. Livestock breeding, primarily hog and poultry raising, is being mechanized. The main branches of animal husbandry—meat and dairy cattle raising, hog raising, and industrial poultry raising—are marked by a high density of livestock per unit of farmland (see Table 5) and by high productivity (see Table 6).

FORESTRY. Forests are one of the country's major natural resources. The timber output averages 15 million cu m a year, with the western regions supplying mainly soft wood and the eastern regions hard wood. Other economic activities include hunting (wild boars, pheasants) and pond fish breeding.

Transportation. The operating length of the country's railroads, the chief means of transportation, is 13,200 km, or 10.3 km per 100 sq km of territory. About one-fifth of the track is electrified. In 1976 railroads transported 276 million tons of freight and 462 million passengers. The electrified trunk line linking Prague, Česká Třebová, Olomouc, Žilina, Košice, and Cierna connects the CSSR with the USSR. As a member of COMECON Czechoslovakia participates in the international economic organization known as the Common Pool of Freight Cars. The country has 73,500 km of hard-surfaced roads, or 60 km per 100 sq km of territory. Road transport is important for passenger traffic; in 1961 motor vehicles transported 1,976,000,000 passengers and 317 million tons of freight. Bus routes connect virtually all the inhabited areas. The Prague-Brno-Bratislava Highway is under construction (1978).

Table 6. Output of principal livestock and poultry products
(thousand tons)

	1960	1970	1976
Meat and fat (dressed weight)	802	1,098	1,322
beef	240	362	415
pork	483	586	728
poultry	45.8	103	141
Milk[1]	4,093	4,978	5,485
Wool (unwashed)	2.5	4.1	3.6
Eggs (million units)	2.267	3.733	4.492

[1]Averaging 2,892 kg per cow in 1976

River transport plays a significant role in foreign trade, with the Danube being used mainly for imports and the Labe for exports. In 1976 some 5.9 million tons of freight were hauled on the country's 458 km of inland waterways. The main ports are Bratislava and Komárno on the Danube and Děčín on the Labe. The country's small merchant marine, based at the Polish port of Szczecin, carried 1.4 million tons of cargo in 1976. There are about 1,500 km of trunk pipelines, including the Druzhba (Friendship) oil pipeline, which extends from the Soviet border to Bratislava and then goes on to Most, the Bratstvo (Brotherhood) gas pipeline, and an international transit gas pipeline from the Soviet frontier to the Prague area, where it branches out toward the German Democratic Republic and the Federal Republic of Germany. Czechoslovak Airlines (CSA) provides air services to all the country's major cities, carrying 1,799,000 passengers in 1976, and makes flights to many countries of Europe, Asia, Africa, and North and South America. There are international airports in Prague (Ruzyné) and Bratislava.

Foreign trade. In per capita foreign trade turnover Czechoslovakia is surpassed only by the German Democratic Republic among the socialist countries. It exports about one-fifth of its industrial output, including about one-third of its machinery output, two-fifths of its output of glass and ceramic ware, one-third of the leather goods and footwear produced, and about one-fourth of its textile output. Table 7 shows the commodity structure of exports and imports.

The foreign trade turnover increased by a factor of 10.5 between 1948 and 1976. More than 80 percent of the imported raw materials and fuel come from the socialist countries, mainly the USSR. The share of the socialist countries in Czechoslovakia's foreign trade turnover rose from 54 percent in 1950 to 72 percent in 1976. The COMECON countries accounted for 67.8 percent and the USSR alone for about one-third of the foreign trade turnover in 1976. The CSSR also maintains extensive trade relations with the advanced capitalist countries and with the developing countries.

The monetary unit is the koruna. By the exchange rate of the State Bank of the USSR, 100 korunas equaled 12 rubles 50 kopeks in January 1978.

Economic regions. When territorial planning was instituted in the mid-1950's, the country was scientifically divided into economic regions. The administrative reorganization of the early 1960's, by which the country was divided into ten administrative regions, was coordinated with economic regionalization. Under the present system of economic regionalization, the CSSR forms a single national economic complex that includes two republic economic complexes, those of the Czech and Slovak socialist republics, which are divided into ten administrative regions and two cities with the status of economic regions (see Table 8).

Standard of living. The comprehensive and rapid development of the national economy in the years of people's rule has ensured a rise in the living standard through increased personal income and social consumption and through a broader satisfaction of cultural needs. The national income doubled between 1960 and 1975, when 70.7 percent of the national income was allocated for the consumption fund. As the general consumption fund increased, so did the share of personal consumption. From 1961 to 1976 wages and other earned income increased by a factor of 2.1, and the earned income of the urban and rural population—of working people in industry and agriculture—was equalized. The average monthly wage of workers and office employees in the state and cooperative sectors of the national economy was 2,304 korunas in 1975, compared to 1,365 korunas in 1960 and 1,937 korunas in 1970. Broken down by branch of the economy, the average monthly wage in industry was 2,340 korunas in 1975 (up from 1,442 in 1960 and 1,967 in 1970); in construction, 2,589 korunas (1,521 and, 2,195); in agriculture, 2,238 korunas (1,113 and 1,806); in transportation and communications, 2,632 korunas (1,461 and 2,239); and in science and scientific services, 2,604 korunas (1,545 and 2,246).

Payments to working people from the social consumption fund—that is, society's expenditures on the social needs of citizens and on free services—increased by a factor of 2.9 from 1961 to 1976. In this period the share of such payments in the income of the population rose from 35 percent to 47.5 percent. State appropriations for public health, education, culture, old-age and health insurance, and family allowances are outstripping the growth in earned income. A program of assistance to large families and maternity support was instituted in the early 1970's. A system of free medical care has been established. Large-scale

Table 7. Commodity structure of exports and imports
(in percent)

	Exports			Imports		
	1960	1970	1976	1960	1970	1976
Machinery, equipment, and means of transportation	45.7	50.4	50	21.7	33.4	35.9
Fuel, mineral raw materials, and metals	19.1	18.6	18.6	27.9	23.5	28.9
Nonedible agricultural raw materials and processed goods, food raw materials, and food products	10.4	7.3	6.8	37.1	24.1	17.7
Manufactured consumer goods	20.4	16.6	17.6	3.4	8.5	7.1
Chemical products, fertilizers, rubber, construction materials, and other products	4.4	7.1	7	9.9	10.5	10.4

housing projects have been built, and measures are being taken to improve the environment. The social security system, which covers the overwhelming majority of the working people (workers, office employees, and members of fishing and agricultural cooperatives), is financed by contributions from organizations and state subsidies. The social security system is administered by the trade unions, whose representatives work with the agencies that allocate pensions.

Table 8. Share of the republics and regions in the area, population, and production output of the CSSR
(in percent)

	Area	Population	Industrial output	Agricultural output[1]
CSSR	100	100	100	100
CSR	61.7	68	74.2	69.2
Prague	0.4	7.9	8.7	—

Central Slovakia	14	9.8	9	6.3
East Slovakia	12.7	8.9	6	7

[1]In 1974

The amount of sickness allowance depends on the length of employment and varies from 60 to 90 percent of the average wage. Women are granted paid leaves of 26 weeks during pregnancy and after childbirth; the leave is extended to 35 weeks for single mothers or in case of the birth of twins. Allowances for the birth of a child and family allowances for children are also paid out of social security funds.

Pension legislation divides all jobs and all workers into three categories, depending on the hazards and difficulty of the work. The social security system provides old-age and disability pensions, pensions for the loss of a breadwinner, meritorious service pensions, and special pensions. The retirement age is 60 years for men (55 years for workers in the first category and 58 for those in the second category), and from 53 to 57 years for women, depending on the number of children the woman has brought up. The size of the pension depends on earnings and term of service. Pensions for disability resulting from general illness are allocated to those who have worked a certain period of time.

A five-day 42.5-hour workweek is standard; for people engaged in hazardous work and for those under 16 years of age the workweek is reduced to 36 hours. Under the law, all workers receive an annual paid vacation. Persons engaged in subsurface, difficult, or hazardous work are granted an additional leave.

Armed forces

The Czechoslovak People's Army, consisting of ground, air, and air defense forces, is headed by the president, who is the commander in chief, and is directly administered by the Ministry of National Defense. It originated in the joint struggle of the peoples of the USSR and Czechoslovakia against a common enemy, German fascism. The first military unit of the People's Army, the Independent Battalion, was formed by Lieutenant Colonel L. Svoboda at Buzuluk (RSFSR) in accordance with the Soviet-Czechoslovak treaty of July 18, 1941. The battalion, which in March 1943 fought at Sokolovo, near Kharkov, was subsequently expanded, first into a brigade and then into a corps. On Oct. 6, 1944, Soviet troops of the Thirty-eighth Army of the First Ukrainian Front, operating jointly with the Czechoslovak Army Corps, captured Dukla Pass and entered Czechoslovakia. The anniversary of this event is celebrated as People's Army Day.

The victory of the socialist revolution in 1948 opened a new phase in the development of the armed forces. A new type of army—well trained, disciplined, organized along modern lines, and equipped with advanced weapons and combat matériel—was created under the leadership of the Communist Party. The armed forces acquire their personnel by conscription, and all men between the ages of 18 and 60 are subject to military service. Officers are trained at the A. Zápotocký and K. Gottwald military academies, at higher military schools run by the different branches of the armed forces, and at military schools in the USSR. The overwhelming majority of the generals and other officers are of worker or peasant background, and more than 80 percent of the officers are members of the Communist Party. Political party work in the army is directed by the Central Committee of the Communist Party through the Main Political Directorate of the People's Army. Military districts and divisions have political agencies, and regiments, battalions, and companies are assigned deputy commanders for political affairs. Since the founding of the Warsaw Treaty Organization in 1955, the People's Army has taken part in joint measures aimed at strengthening the Joint Armed Forces in order to ensure peace and security in Europe.

Health and social welfare

Medicine and public health. In 1976 the country had a birthrate of 19.2 and a mortality rate of 11.4 per 1,000 population; infant mortality was 20.8 per 1,000 live births. The corresponding figures for 1946 were 22.7, 14.1, and 108.8. The average life expectancy is 70.3 years: 66.9 years for men and 73.7 years for women. Cardiovascular diseases, malignant neoplasms, and diseases of the respiratory system are the leading cause of illness and death. Among the more common infectious diseases are scarlet fever, measles, and epidemic hepatitis. The incidence of tuberculosis has declined sharply, poliomyelitis has been completely eradicated, and the incidence of diphtheria has been reduced to isolated cases.

Under the existing state system of public health the entire population receives free medical care and free medicine. The general protection of health is regulated by the public health law of 1966. The Public Health Council sets the country's public health policy, which is then administered by the Ministry of Health of each republic. In 1974 there were 229 general hospitals (almost all of them attached to polyclinics), 22 tuberculosis hospitals, three institutes of rehabilitation therapy, 36 sanatoriums, 131 spa sanatoriums, 21 research institutes, 14 first-aid stations, and 136 hygiene and epidemiological stations. Other medical facilities included

370 regional and 60 factory polyclinics, 2,700 district dispensaries, and 78 women's and 2,500 children's consultation clinics. In 1976 the various medical institutions had a total of 183,000 hospital beds, or 12.3 per 1,000 population, compared to 110,100 beds, or 9.9 per 1,000 population, in 1948.

In 1976 there were 42,300 doctors, or one per 354 inhabitants (9,000 doctors, or one per 1,300 inhabitants, in 1946), 1,100 dentists, and 6,100 pharmacists. Intermediate medical personnel numbered 105,600 persons in 1973. Training is given at ten medical and two pharmacy faculties, four institutes for the advanced training of doctors, pharmacists, and intermediate medical personnel, and 78 medical schools graduating intermediate medical personnel. Public health appropriations have increased from 4 billion korunas in 1950 to 20 billion korunas in 1976, or 7 percent of the state budget and of the budget of the national committees.

The country's 60 spas had 32,500 beds in 1976, compared to 17,300 beds in 1948. The most famous spas are the balneological resorts of Karlovy Vary, Mariánské Lázně, Teplice, Poděbrady, Janské Lázně, Jachymov, and Luhačovice, the balneological and pelotherapy resorts of Františkovy Lázně and Piešťany, and the climatic resorts of Štrbské Pleso, Tatranská Lomnica, and Tatranská Polianka.

IA. D. POGORELOV

Veterinary services. A number of animal diseases have been eradicated in the postwar period: sheep pox in 1950, glanders in 1954, dourine in 1953, equine infectious anemia in 1965, contagious agalactia in 1946, brucellosis in 1965, and bovine tuberculosis in 1968. In 1976 there were four outbreaks of Newcastle disease, 433 outbreaks of rabies, two outbreaks of hog cholera, and three outbreaks of anthrax. Other diseases recorded that year included swine erysipelas, fowl cholera, myxomatosis, swine influenza, Marek's disease, fowl tuberculosis, infectious porcine encephalomyelitis, blackleg, bovine rhinotracheitis, coccidiosis, infectious atrophic rhinitis of swine, fowlpox, fowl leukemia, pullorosis, fascioliasis, echinococcosis, cysticercosis, and mastitis.

Since 1969 veterinary services have been directed by the veterinary administrations under the ministries of agriculture and food of the constituent republics. Based in Prague and Bratislava, the veterinary administrations are responsible for organizing the veterinary care of livestock. The office of chief veterinarian under the Federal Agriculture and Food Committee, which is advised by a federal veterinary council, coordinates antiepizootic measures, protects the country from the importation of infectious animal diseases, supervises the movement of animals within the country, and maintains contacts with foreign veterinary services and with international veterinary organizations. There were 2,500 veterinarians in Czechoslovakia in 1976. Antiepizootic services are provided without charge, and standard fees for veterinary treatment are set by the government.

Veterinarians are trained by the veterinary faculties of the agricultural universities in Brno and Košice, which also enroll students from Africa, Asia, and Latin America. In addition, there are three institutes for the advanced training of veterinarians. Veterinary research is conducted at the Central State Veterinary Institute, based in Prague and Bratislava, the Scientific Research Institute in Brno (Medlanki), the Central State Diagnostic Institute in Prague, the State Institute for the Control of Biological and Veterinary Preparations in Brno, the State Veterinary Institute of Wild Animals in Jihlava, the Virology Institute of the Czechoslovak Academy of Sciences in Bratislava, and regional research laboratories. Veterinary biologicals are produced at the Biovet enterprises in Terezin, Ivanovice na Hane, and Nitra.

S. I. KARTUSHIN

Education

Written sources attest to the existence of monastery schools in Bohemia and Moravia in the tenth century and in Slovakia in the early 12th century. The first urban schools were established in the 12th and 13th centuries. Charles University, founded in Prague in 1348, greatly influenced the development of Czech national culture and education. In the 15th and 16th centuries Latin was the language of instruction; only the brotherhood schools, founded in the 16th century by the Bohemian Brethren, gave precedence to the native tongue. The writings of J. A. Komenský (Comenius) were associated with the educational work of the Brethren in the 17th century.

Under Hapsburg rule, when the school system in the Czech lands was organized and developed as an integral part of the Austrian system, German was forcibly imposed on the populace. Compulsory education for children from six to 12 years of age was introduced under the school reform of 1774, which established several types of schools: "trivial" schools, offering one or two years of primary instruction; three-year "main" schools, which prepared the pupils for further studies; and two- to four-year "normal" schools, whose curriculum augmented the program of the main school. In the late 18th and first half of the 19th centuries the school network expanded considerably throughout Austria-Hungary. The development of industry obliged the ruling classes to broaden the scope of education. A law enacted in 1869 provided for compulsory eight-year schooling for children six to 14 years of age. The church gradually lost its hold over education.

The establishment of the bourgeois Czechoslovak republic in 1918 brought few changes to the school system, which retained its class character. In the 1930–31 school year only 11 percent of the secondary-school students were of working-class background, although workers constituted at that time almost 60 percent of the population. During the fascist German occupation the number of secondary schools declined sharply, and all higher educational institutions were closed on Nov. 17, 1939. Progressive instructors and students were subjected to repression. After the liberation of Czechoslovakia in 1945 and the beginning of socialist construction, a unified state school system was set up, and the goals and tasks of instruction changed fundamentally. A law enacted in 1948 nationalized all educational institutions and separated the school from the church.

The present education system provides for nurseries for children up to the age of three and kindergartens for children three to five years of age. In the 1976–77 school year the country's 9,554 kindergartens were attended by 522,000 children. Instruction is compulsory for children between six and 16 years of age. The eight-year basic school, enrolling children from six to 14 years of age, consists of a primary level (grades 1 to 4) and an incomplete secondary level (grades 5 to 8). In the 1976–77 school year there were 8,550 basic schools with an enrollment of more than 1,882,000. Upon completing the basic school, the student may enroll in (1) a four-year complete secondary school, called a *Gymnasium*, (2) a two- to four-year vocational school training skilled workers for various branches of the national economy, or (3) a secondary vocational school offering three or four years of instruction. In the 1976–77 school year there were 339 *Gymnasiums* with 137,100 students, and about 400,000 students attended secondary vocational schools of all types.

The system of higher education includes universities, institutes, and higher schools with a course of instruction lasting four to six years. In the 1976–77 academic year there were 36 higher educational institutions with 168,300 students. The largest of these institutions are the universities of Prague (founded 1348), Bratislava (1919), Brno (1919), Olomouc (1576), and Košice (1959); the technical universities in Prague (1707), Bratislava (1938), and Brno (1899); the higher schools of chemical technology in Prague (1952) and Pardubice (1950); the schools of economics in Prague (1953) and Bratislava (1940); the agricultural colleges in Prague (1906), Brno (1919), and Nitra (1946); the Academy of Arts and the Academy of Fine Arts in Prague; the Polytechnical Institute and the L. Janáček Academy of Music and Dramatic Art in Brno; and the Higher School of Fine Arts in Bratislava.

Many of the country's largest libraries are in Prague: the State Library of the Czech Socialist Republic (founded 1958; 4.6 million volumes in 1976), the Main Library of the Czechoslovak Academy of Sciences (1952; more than 700,000 volumes), the National Museum Library (1818; 2.4 million volumes), the Public Library (1891; 2,048,000 volumes), the State Technical Library (1707; 724,000 volumes), and the State Pedagogical Library (1919; 363,000 volumes). Outside the capital, major libraries include the University Library in Bratislava (1919; 1,563,700 volumes), the Matice Slovenská in Martin (1863; 1,850,000 volumes), the University Library in Brno (1815; 1,689,000 volumes), the State Technical Library (1899; 1.1 million volumes) in Brno, and the State Scientific Library in Košice (1657; 846,500 volumes).

The most important Prague museums are the National Museum, the National Gallery, the Museum of the Capital City of Prague, the V. I. Lenin Museum, the Klement Gottwald Museum, the State Jewish Museum, the ethnographic, agricultural, and anthropological museums, the J. A. Komenský Pedagogical Museum, and the B. Smetana and A. Dvořák museums. Among other fine museums are the Slovak National Museum, the Slovak National Gallery, and the Municipal Museum in Bratislava, and the Moravian Museum, the Moravian Gallery, and the Municipal Museum in Brno. There are also several regional museums of local lore.

G. A. KASVIN

Science and scientific institutions

Natural and technical sciences. TO THE LATE 18TH CENTURY. In the Middle Ages urban handicrafts, chiefly cloth-making and metalworking, construction, metallurgy, and mining flourished in the area now known as Czechoslovakia. In the 13th and 14th centuries important mineral deposits were discovered, notably silver ore at Kutná Hora and Banská Štiavnica and copper ore at Banská Bystrica. From the 14th century the focal point of scientific development in the Czech lands was Charles University, whose instructors included the mathematician and medical man Křišťan of Prachatice, and the astronomer and botanist Jan Šindel. The German astronomer and mathematician Regiomontanus worked for a time at the first Slovak university, which was founded in Bratislava in 1467 and existed until 1591. The first Czech printing press was founded in Plzeň around 1468, and another printing press was established in Prague in 1480. One of the first books to be printed in the Czech lands was the medical work *Vetularius* by Albík of Uničov. The Byelorussian printer F. Skorina worked in Prague from 1517 to 1519.

Several major works devoted to practical achievements appeared in the 16th and 17th centuries. G. Agricola, who lived in Jachymov, wrote *On Mining and Metallurgy*, which for two centuries served as a textbook and reference work. The works of Matthesius and L. Ercker contained information on geology, mineralogy, and assay analysis. V. Křička, the builder of the "singing fountain" on Hradčany Hill in Prague, wrote a Czech-language handbook on foundry work (first published in 1947). The eminent physician J. Kamenický wrote on liver diseases, and Jordan of Klausenburk studied therapeutic mineral springs, including those at Karlovy Vary.

Renaissance ideas influenced the work of Tadeáš Hájek, a physician, botanist, and astronomer who expounded the heliocentric system; A. Zalužanský, the author of the first Czech work on botany (1592); and J. Jessenius, a naturalist and the physician of Rudolph II. A scientific center of European renown, attracting such famous scientists as Tycho Brahe and J. Kepler, emerged at Rudolph's court in Prague in the late 16th and early 17th centuries. The *Czech Cosmography*, published in 1554, contained geographical information about many countries. A university was founded in Olomouc in 1576.

The loss of political independence and the stifling of the national culture had a detrimental effect on the further development of science in the Czech lands. Charles University was reorganized and merged with a Jesuit college in 1654. The reopened educational institutions at Trnava (1635) and Košice (1657) regarded as their primary goal the restoration of Catholicism. The best known of the few scientists who worked alone were Marci von Kronland, whose studies in optics included an explanation of the rainbow, and J. Dobřenský, who initiated the clinical teaching of medicine in Bohemia. In the 1620's and 1630's blasting with gunpowder came into use in mining.

An engineering school was established by the estates in Prague in 1707, and in 1751 an astronomical and meteorological observatory was built in the city through the efforts of J. Stepling. The world's first higher mining school was founded in Banská Štiavnica, Slovakia, in 1763–64 and reorganized as a mining academy in 1770. Its faculty included J. K. Hell, who had invented a hydraulic engine in the 1730's and 1740's. Other prominent 18th-century men of science were the physician and naturalist J. K. Boháč, who investigated the possibility of using electricity in therapy, the inventor P. Divisch, who built the first grounded lightning rod in Europe (1754), and J. Tesánek, the author of several works on number theory.

LATE 18TH AND FIRST HALF OF THE 19TH CENTURIES. The last decades of the 18th century and the first half of the 19th century, the period known as the National Renaissance, saw the founding of several new learned and higher educational institutions. The Bohemian Society of Sciences was founded in Prague in 1784; it was renamed the Royal Bohemian Society of Sciences in 1790. A royal-estate technical school was founded in Prague in 1806, later becoming a polytechnical institute, and a higher school of forestry was established in Zvolen in 1807. The Museum of the Kingdom of Bohemia (founded in 1818, now the National Museum) and the Matice Česká played an important role in strengthening Bohemia's scientific forces and in organizing research. The Slovak Learned Society was founded in Trnava in 1793.

The late 18th and the first half of the 19th centuries were marked by a number of outstanding scientific achievements. F. A. Reuss embarked on one of the first mineralogical and balneological studies of the mountain regions of Bohemia. His work was continued by his son A. E. Reuss. J. Krejčí, who studied the Ore Mountains, is regarded as the founder of Czech geology. K. Šternberk made a major contribution to the classification of fossil plants, and F. M. Opiz laid the foundation for the study of the flora of Bohemia. A prominent place in the development of modern Czech science belongs to J. S. Presl, who with his brother K. B. Presl published the *Flora of Bohemia* (1819), the first such work, and a fundamental work on mineralogy (1837). Systematically developing Czech scientific terminology, Presl was one of the founders of Czech scientific writing. In 1821, Presl and J. Jungmann undertook the publication of the first Czech encyclopedia. G. Reuss produced the first botanical description of Slovakia, and L. Šmarda published the three-volume compendium *Geographic Distribution of Animals* (1853).

Several Czech physiologists and physicians came to prominence in the late 18th and early 19th centuries. G. Procháska was one of the founders of the reflex theory, which subsequently became the basis of neurophysiology. The internationally acclaimed work of J. E. Purkinje (Purkyně) had a great impact on the development of cytology, anatomy, and embryology and led to the formulation of the cell theory. B. Bolzano introduced several important concepts of mathematical analysis.

There were also advances in technology and in the technical sciences. In the late 18th century I. Born proposed a method of recovering gold and silver by amalgamation. F. J. Gerstner, who offered original solutions to several practical problems of mechanics, improved mine hoisting machines. J. Ressel designed and successfully tested (1826) a screw propeller for ships. In the 1820's a horse-drawn railroad was built from České Budějovice to Linz. The first railroad, connecting Prague with Olomouc, went into opertion in 1845.

FROM THE MID-19TH CENTURY TO 1918. In the years between the Revolution of 1848 and the emergence of the Czechoslovak state the political climate was not conducive to scientific endeavor. Among the scientists who emigrated abroad were the biologists and physicians K. von Rokitansky, J. Škoda, F. von Hebra, and F. Chvostek and the mechanical engineer A. Stodola. The disparity between scientific development in the Czech lands and in Slovakia became increasingly apparent. Few educational or learned institutions were established in Slovakia: an agricultural school was opened in Liptovský Hrádok in 1871, an industrial school was organized in Krukotin in 1875, and a society of physicians and naturalists was founded in Bratislava in 1856. The Matice Slovenská, founded in 1863, was closed in 1875. Despite the difficulties, D. Štúr continued his research in zoology and paleontology, and A. Kmeť and J. Holuby pursued their work in botany.

In the Czech lands learned societies were formed in several branches of science: medicine (1862), mathematics (1862), chemistry (1871), geology (1884), and geography (1894). A committee for the study of the natural resources of the Czech lands was established at the National Museum in 1864. When the Prague Polytechnical Institute was divided into a Czech and a German institute in 1863, the Czech institute became the first higher educational institution to use Czech as the language of instruction. In 1882 the University of Prague was likewise divided into two universities. The newly formed Czech educational institutions engendered several schools of 20th-century Czechoslovak

scientific thought. By the turn of the 20th century Czech-language scientific works existed in virtually all fields. The Czech Academy of Sciences and Arts was founded in 1890.

Important work in geology was done by J. Barrande (corresponding member of the St. Petersburg Academy of Sciences from 1877), who settled in Bohemia in 1831. Barrande's 24-volume monograph is considered a classic of 19th-century paleontology. F. B. Pošepný did pioneering work on the theory of ore deposits. C. Purkyně and J. V. Daneš laid the foundation for Czech geomorphology, and K. Kořistka compiled geographical maps of most of Bohemia. Prominent biologists included the botanist L. Čelakovský, an exponent of Darwinism, and the zoologists A. Frič and F. Vejdovský, who wrote on animal anatomy. G. Mendel, the founder of genetics, conducted his experiments in a monastery in Brno, publishing in 1866 in the proceedings of the local natural science society the *Experiments in Plant Hybridization*, a classic work that won world recognition in the 20th century. Advances in chemistry included B. Brauner's studies on rare-earth elements, V. Šafařík's research in inorganic chemistry, and J. Stoklasa's work on the biochemistry of plants and agricultural chemistry. Important work in medicine was done by the microbiologist J. Hlava, the surgeon K. Maydl, and the gynecologist and urologist K. Pavlik. J. Jansky won international acclaim for his description of blood groups in 1907.

The leading mathematicians of this period were Eduard Weyr, who wrote on the projective theory of curves, his brother Emil Weyr, and F. J. Studnička, who worked on the theory of determinants. M. Lerch was noted for his works on number theory and the theory of special functions.

The metallurgy industry benefited from F. Wald's work in physical chemistry. Various problems of extracting minerals were solved by the engineers E. Horovský and J. Hrabák, the latter recognized as the founder of Czechoslovak mining mechanics. F. Křižík built the first electric power plant in Bohemia in 1888 and an electrified railroad in 1903. A Czech school of construction engineering emerged under J. Šolín, and the well-known Czech school of sugar refining was established by K. Preis and K. Andrlík. Other technical achievements included J. Husnik's development of phototype in 1868 and F. Hruska's invention of a honey extractor in 1865.

FROM 1918 TO 1945. After independence, the Czechoslovak government established research institutes in Prague in geology (1919, under C. Purkyně), hydrology (1919), and meteorology (1920). Several research institutes and laboratories were set up at Charles University. The university that was founded in Brno in 1919 acquired a natural science faculty the following year. The Czechoslovak Scientific Research Council, founded in 1919, was essentially a representative body. In Slovakia, the J. A. Komenský University was founded in 1919 in Bratislava (a natural science faculty was added in 1938), and the Matice Slovenská was revived. The P. J. Šafařík Learned Society was founded in 1926 to promote scientific work. State appropriations for research, generally small, were reduced to a bare minimum during the economic crisis of 1929–33.

The interwar period saw major achievements in chemistry. J. Heyrovský (elected to the Academy of Sciences of the USSR in 1966) developed the polarographic method in 1922. E. Votoček's investigations in analytical chemistry and the chemistry of sugar and J. Dubský's work on complex compounds were widely acclaimed. The mathematician E. Čech did pioneering work in projective differential geometry. F. J. Studnička, the mathematician, was a tireless popularizer of science. F. Záviška's works dealt with problems of crystallography and hydrodynamics, and V. Dolejšek did research on X rays.

The contributions of Czechoslovak biologists were also significant. B. Němec was one of the founders of experimental cytology. In the tradition of the national school of physiology, E. Babák studied the adaptation of organisms under extreme conditions. V. Ružička won recognition for his work in genetics. The surgeon J. Diviš and the cardiologist V. Libenský did outstanding work in medicine. V. Dedina directed the publication of a multivolume regional geography of Czechoslovakia (1929–31). F. Ulrich and R. Nováček conducted research in mineralogy and geochemistry.

The occupation of the country by fascist troops severely undermined Czechoslovak science. Scientific institutions and universities were closed. The clerical-fascist regime in Slovakia established, for demagogic purposes, the Slovak Academy of Sciences and Arts in 1943. Záviška, Dolejšek, Ulrich, Nováček, and many other scientists perished during the occupation.

SINCE 1945. After the liberation of Czechoslovakia by the Soviet Army, and especially after the victory of the working people in 1948, science was confronted with fundamentally new tasks related to the development of the material and technical basis for socialism and the socialist transformation of society. The higher educational institutions that had been closed were reopened, and new ones were founded; a network of research institutions was established to serve various branches of the national economy. The founding of the Czechoslovak Academy of Sciences in 1952 was followed by the creation of the Slovak Academy of Sciences the next year. The network of scientific institutions steadily expanded, and the coordination of scientific work became more precise. Research, planning, and design organizations were founded not only in Prague and Bratislava but also in many other cities, including the industrial centers of Brno, Ostrava, Gottwaldov, and Košice. The higher educational institutions increased their commitment to research.

Outstanding achievements in mathematics have included E. Čech's and V. Jarník's work on the theory of functions and V. Kořínek's research on group theory. Czechoslovak mathematicians have turned to branches that hitherto received little attention: differential equations, functional analysis, probability theory and mathematical statistics, mathematical logic, and some fields of cybernetics. They are also working on problems of applied mathematics.

A conference of Czechoslovak physicists held in 1951 defined for the first time the basic directions of physics research in the country. The study of X rays continues. Significant work is being done on the physics of semiconductors and ferrites, the magnetic properties of metals, crystallography, low-temperature physics, and superconductivity. Research on the physics of elementary particles and the atomic nucleus has begun with the help of Soviet specialists. In 1957 the first Czechoslovak nuclear reactor was put into operation at Řež. Research on plasma physics, using a Tokamak unit, has been initiated in cooperation with the Academy of Sciences of the USSR. Several kinds of electronic microscopes and other unique instruments have been developed, including instruments for the study of the structure and energy states of surfaces. Astronomical research, much of it conducted at the Ondřejov Astronomical Institute, has focused on interplanetary matter (V. Guth) and on the physics of the sun, stars, and stellar systems.

In chemistry, J. Heyrovský received the Nobel Prize in 1959 for his work on the theory and technology of polarography. Two of Heyrovský's students have also won recognition: R. Brdička for his work on chemical kinetics and D. Ilkovič for his work on thermodynamics. R. Lukeš and his associates have made a major contribution to the chemistry of natural and heterocyclic compounds. Geologists are studying minerals and ores (F. Slavík). Problems of tectonics (V. Zoubek, elected to the Academy of Sciences of the USSR in 1976) and engineering geology are being resolved in conjunction with large building projects. A geological map of the CSSR (1:200,000 scale) has been published, and geomorphological maps have been compiled. A national atlas has been published. F. Vitásek has written one of the most comprehensive textbooks of physical geography (4th ed., 1956–65). Research is under way on landscape science (J. Demek) and on the protection of the environment.

Czechoslovak biologists have done significant work in plant physiology, geobotany, paleobotany, microbiology (D. Blaškovič, elected to the Academy of Sciences of the USSR in 1966), virology, molecular biology (F. Herčík), and biophysics (J. Šterzl). In the medical sciences promising research is being done in histology (F. Studnička), medical biochemistry, endocrinology, human physiology and pathophysiology (V. Laufberger), and medical microbiology. Progress in neurology has been achieved by J. Hrbek (elected to the Academy of Medical Sciences of the USSR in 1969), and several branches of surgery have been advanced by K. Šiška (elected to the Academy of Sciences of the USSR in 1971 and to the Academy of Medical Sciences of the

USSR in 1969) and by F. Burian. Expanding research in pharmacology has led to the discovery of a number of cytostatic and psychopharmacological drugs. Other medical research fields include oncology (V. Thurzo) and pediatrics (J. Houštěk). In the agricultural sciences research has focused on the physiology and genetics of farm animals, general and special zootechny, agronomy, soil science, forestry, land reclamation, and the mechanization of agricultural production.

The technical sciences are flourishing, particularly fields that apply to machine building: applied mechanics (J. Kožešník, elected to the Academy of Sciences of the USSR in 1971), the theory of elasticity and plasticity and the theory of welding (J. Čabelka), and the theory of hydraulic machines (J. Hýbl). O. Maštovský's research and designs have improved the parameters of power-engineering machinery. P. Ryš is doing important work in materials technology and S. Bechyně in construction mechanics. Problems of water management are being studied by T. Eždik. As a result of special engineering studies of rocks and the methods of breaking them, new mineral deposits are being worked and the output of minerals has increased. There has been notable progress in power engineering (J. Řeznicek), electronics and radio engineering (J. Stránský), the technology of strong currents (B. Heller), and the technology of semiconductor materials (Z. Trousil). A computer industry is being established. The products of several industries are noted for their high technical level, namely motor vehicles, including the heavy Tatra trucks, the electric locomotives of the ČKD Plant, river boats, means of communication, and equipment for the leather footwear and textile industries.

Czechoslovak scientists and engineers are working with specialists from the USSR and other socialist countries at the Joint Institute for Nuclear Research and on projects of the Interkosmos Program. V. Remek, the first Czechoslovak astronaut, took part in the flight of the Soviet orbital research complex Salyut 6–Soyuz in March 1978. During the flight the international crew conducted several joint studies and experiments prepared by specialists in the USSR and the CSSR. The scientific and technical cooperation within COMECON encompasses several branches of machine building, metallurgy, power engineering, medicine, and public health. Czechoslovak scientists have taken part in many international programs, among them the international Years of the Quiet Sun, the International Hydrological Decade, the International Biological Program, and the International Project on the Upper Mantle of the Earth. Cooperation with many international scientific organizations is expanding.

Social sciences. PHILOSOPHY. Medieval Czech philosophy was dominated by Thomist scholasticism, whose influence began to wane in the early 15th century with the rise of the antifeudal revolutionary Hussite movement. The forerunners of Hussitism were Matthew of Janov, Vojtěch Raňkův, and Thomas of Štítný. Jan Hus, the ideologist of the Czech Reformation, preached a humane interpretation of "god's law" as the norm of social relations and social justice. The revolutionary wing of the Hussite movement, the Taborites, who repudiated feudalism, held the authority of reason to be the highest principle. The Taborites' views contained elements of pantheism. P. Chelčický, one of the ideologists of the Taborites, rejected the feudal division of society into estates and proposed a utopian program of social reform, to be achieved by passive resistance.

The next phase in Czech philosophy was marked by a blending of Reformation ideas with humanism, which was beginning to speculate about the development of the natural world and society. The humanist tradition in Czech philosophy culminated in the work of J. A. Komenský (Comenius), who held that education and upbringing must be based on enlightened reason and be imbued with the spirit of universal harmony.

In Slovakia, 15th-century philosophy developed under the influence of Renaissance and Reformation doctrines. Founded in the latter half of the 17th century by J. Bayer and I. Caban, the Prešov school was influenced by F. Bacon's ideas and P. Gassendi's atomism. From the mid-18th century Slovak philosophical thought flourished at the University of Trnava and in learned societies. Such Slovak thinkers as J. Laurentzy, J. Feješ, and M. Steigel attacked religious prejudice, affirmed the independence of thought, and propagated deism, empiricism, and Kantianism.

With the development of capitalist relations in the late 18th and first half of the 19th centuries, Czech Enlightenment learning, based on the rational-critical method, found ardent champions in J. Dobrovský and G. Prochaska. The ideologists of the Czech and Slovak National Renaissance—J. Jungmann, F. Palacký, and J. Kollár—espoused the dialectical concepts of J. G. Herder, F. Schelling, and G. Hegel. The Czech mathematician and philosopher B. Bolzano proposed a methodological analysis of the logical foundations of science. Under the influence of Hegelianism the bourgeois-democratic thinkers L. Štúr, J. M. Hurban, F. Klácel, and A. Smetana developed a philosophy of nationalism, history, and art and expounded ideas of freedom and social utopia. The radical democrats E. Arnold, K. Sabina, and J. V. Frič called for progressive social and political changes.

In the latter half of the 19th century the ideas of the German philosopher J. F. Herbart attracted many adherents to the Czech lands and Slovakia. Another major trend, positivism, had a considerable influence on T. G. Masaryk, an ideologist of bourgeois reformism and an opponent of Marxism.

Marxist ideas, filtering into the Czech labor movement in the 1870's and spreading to Slovakia in the 1880's, were disseminated by the "pioneers" of socialism J. B. Pecka and L. Zápotocký. The activity of B. Šmeral was of great importance for the growth of the labor movement and the spread of Marxist-Leninist ideology. In the period of the bourgeois republic Czech and Slovak Marxists, led by K. Gottwald, worked on problems of Marxist-Leninist philosophy. The foundation for a Marxist tradition in philosophy and sociology was laid by Z. Nejedlý and L. Štoll in the Czech lands and by L. Szántó and A. Sirácky in Slovakia.

Contemporary Marxist-Leninist philosophers and sociologists, notably I. Hrušovský, R. Richta, V. Ruml, L. Svoboda, V. Filkorn, and V. Cirbes, are studying the development of a socialist society, the scientific and technological revolution, and philosophical and logical problems of modern science. They are combating bourgeois ideology and revisionism, openly manifested in 1968–69 in the attacks of some philosophers and sociologists on the basic principles of the Marxist-Leninist world view.

Czechoslovak philosophers and sociologists are working closely with scholars in the USSR and other socialist countries, participating in joint conferences, research, and publications. Philosophical and sociological research is conducted by the philosophy departments of the Czechoslovak and Slovak academies of sciences, at the Higher School of Political Studies attached to the Central Committee of the Communist Party of Czechoslovakia, at institutes of Marxism-Leninism, and by the philosophy faculties of the universities in Prague, Bratislava, and Brno. The leading philosophical and sociological journals are *Filosofický časopis* (since 1953), *Sociologický časopis* (since 1965), *Nová mysl* (since 1947), *Slovenský filozofický časopis* (founded 1946; since 1966, *Filozofia*), and *Sociológice* (since 1969), the last two journals being published in Slovakia.

HISTORY. In the Czech and Slovak lands early feudal historical literature originated in the late ninth and early tenth centuries, when hagiographies, in Old Church Slavonic and Latin, were written about the Slavic educators Cyril and Methodius, the Přemyslid rulers Ludmila and Václav (Wenceslas), and the Prague bishops Vojtěch (Adalbert) and Procopius. The finest example of Czech annal writing of the early Middle Ages is the Czech Chronicle, written in Latin in the early 12th century by Cosmas of Prague, dean of the St. Vitus Cathedral. The Bratislava Annals of the late 12th century are also written in Latin. The first historical work to be written in Czech was the rhymed Dalimil Chronicle of the early 14th century. The Chronicle of Abbot Petr Žitavský, written in Latin and covering events down to 1338, dates from the same period.

The highly polemical historical writing of the Hussite period (first half of the 15th century) incorporated such new professional techniques and forms as document citations, diary entries, and dialogues and reflected the more diverse social background of the authors. The chronicles of Vavřinec z Březové, Petr z Mladoňovic, and Mikuláš z Pelhřimova, as well as other historical works, mirrored the bitter social, political, and ideological conflict of that time. After the defeat of the Hussite movement, Reformation and humanist ideas were expounded by such 16th-century writers as Sixt z Ottersdorfa and Jan Blahoslav, whose principal

adversary was Václav Hájek z Libočan, the spokesman of the Czech Catholic nobility. The most important 16th-century Slovak historian was M. Rakovský, who wrote mainly in verse. After the onset of Catholic reaction in the 1620's, the traditions of progressive historiography were carried on by P. Stránský, P. Skála, and B. Balbín. The 18th century writers M. Bel and F. A. Kollár paved the way for the Slovak historiography of the National Renaissance.

The development of capitalist relations in the late 18th and first half of the 19th centuries promoted a rapid expansion of historical studies. The historians of the early period of the National Renaissance, notably G. Dobner, J. Dobrovský, and F. M. Pelcl, initiated the scholarly critique of sources and produced the first historical works aimed at instilling national consciousness. J. Papánek and J. Fándly expressed Enlightenment views in their works on Slovak history. P. J. Šafařík's *Slavic Antiquities* (1837) and *Ethnography of the Slavs* (1843) were the first scholarly investigations of the early history of the Slavic peoples. The greatest historian of the first half of the 19th century was F. Palacký. Representing the bourgeois national-liberal wing of the "romantic" trend in Czech historiography, Palacký and his numerous followers were especially interested in the Hussite movement, which they considered a heroic chapter of their national history. Their works, however, did not reveal the social preconditions of the Czech people's struggle against national and religious oppression. Unlike them, K. Sabina, E. Arnold, and other radical democrats perceived the social roots of the Hussite movement and understood the revolutionary nature of the peasant war led by J. Žižka. The historical-philosophical and political writings of L. Štúr had a profound effect on 19th-century Slovak historiography.

The defeat of the Revolution of 1848–49 reinforced the conservative and pro-Hapsburg tendencies in Czech bourgeois historiography, whose leading exponent was V. Tomek. By the 1860's, however, liberal positivism had become the dominant school in historiography. Led by A. Gindely, J. Kolouŝek, K. J. Erben, and J. Emler, the historians of this school wrote basic works on national history and collected and published a large number of official documents and legal records. In Slovakia, the foremost representative of romantic historiography, which held sway down to the end of the 19th century, was F. V. Sasinek.

The "pure positivist" school of Czech historiography, founded by J. Goll, expanded the subject matter of research to include international relations and social and economic history, broadened the chronological scope to encompass the pre- and post-Hussite periods, enriched the study of sources, and began applying the comparative historical method. The primary weakness of the positivist historians, notably V. Novotný, J. Šusta, G. Friedrich, Z. Winter, K. Krofta, B. Mendl, and V. Chaloupecký, was their tendency to concentrate on individual problems of history. The Goll school, which in the late 19th and early 20th centuries dominated first Czech and then Czechoslovak historiography, underwent considerable evolutionary changes. Some of Goll's students increasingly confined themselves to simply describing historical events and ascertaining facts, reducing comparative history to the "theory of influences." The tumultuous events of the first decades of the 20th century caused a deep ideological and political rift between Goll's students and followers. While J. Pekař took an ultraconservative approach to the major periods of medieval and modern Czech history, Z. Nejedlý, another of Goll's students, criticized the positivists for restricting the tasks of historical research, for refusing to make philosophical generalizations, and for attempting to make history a "pure science."

Other major scholarly contributions at the turn of the century included the early works of the archaeologist and historian L. Niederle, the first works on the modern political history of the Czech lands (A. Srb), the first studies devoted to political, social, national, and cultural problems of Austro-Hungarian history (Z. Tobolka), and the first works on the history of the Czech labor movement (L. Zápotocký, C. Horáček, and B. Šmeral).

After the establishment of the bourgeois Czechoslovak republic, although Czech and Slovak medieval history continued to engross bourgeois scholars, they showed a much greater interest in modern and contemporary national history, particularly in the restoration of the national state. Important work in post-medieval history was done by Tobolka, K. Kazbunda, J. Opočenský, K. A. Medvecký, and J. Botto. There appeared numerous works on "legion" history, dealing with the Czechoslovak political organizations and military units in the Entente countries during World War I. The most influential scholars working on this subject—F. Šteidler, J. Papoušek, J. Kudela, and J. Werstadt—upheld the concept of "national liberation" expounded in the works of Masaryk and other political leaders of the governing bourgeois Hrada group. The social-reformist historians, notably F. Soukoup and I. Dérer, also did not transcend Masaryk's concept, although they devoted much attention to the history of the labor movement. A right-wing, conservative alternative to the official concept of national liberation was propounded by K. Kramář and his followers F. Zuman and A. Kalina. The sole exponent of left-wing legion literature was J. Kratochvíl.

Nejedlý's scholarly and publicistic work promoted the development of progressive views on national history and acquainted the Czechoslovak public with the scientific and cultural achievements of the Soviet Union. The Marxist trend in Czechoslovak historiography was represented mainly by the writings of Communist Party leaders, notably Šmeral, K. Kreibich, J. Šverma, and K. Konrad. In the second half of the 1930's young historians sympathetic to Marxism, among them V. Husa, O. Říha, and V. Čejchan, rallied around the journal *History and Modern Times*.

In the first years after the liberation of Czechoslovakia from the fascist occupation, although bourgeois historians remained influential in education and scholarship, they were already opposed by a group of Marxist historians who were advocating radical changes in the methodology, subject matter, and methods of historical research. Nejedlý formulated the basic principles of a Marxist view of Czechoslovak history.

The prerequisites for intensive Marxist research were created in Czechoslovakia after 1948, when historians began working on problems and periods of national history that had been either totally ignored or distorted in bourgeois historiography, and new sources were made available to scholars. Central problems relating to the ethnogenesis of the Slavs and to the history of the primitive communal system in the Czech lands and Slovakia have been studied by Nejedlý, J. Bem, J. Filip, J. Eisner, J. Poulík, and B. Chropovský. The origins of feudalism and capitalism and the modern national liberation and labor movements have been investigated by Husa, Gosiorovský, Říha, D. Rapant, F. Roubík, B. Varsik, Z. Fiala, J. Janáček, R. Urbánek, J. Purš, J. Křížek, J. Kočí, and P. Ratkoš. Many diverse problems pertaining to contemporary Czechoslovak and world history, to international relations, and to the history of the Communist Party of Czechoslovakia have been studied by J. Veselý, Gosiorovský, L. Holotík, Z. Snitil, V. Plevza, J. Hrozienčík, V. Král, I. Krempa, M. Kropilák, and Č. Amort. Monographic research has permitted the publication of such collaborative syntheses as the *Atlas of Czechoslovak History*, the *Survey of Czechoslovak History*, and the *History of Slovakia*, as well as surveys of the history of the Communist Party and the foreign policy of Czechoslovakia and surveys of the history of Czech-Russian and Czechoslovak-Soviet relations.

Some of the historical works and "historical journalism" produced in 1968–69 betrayed right-opportunist and antisocialist tendencies that essentially represented attempts at a bourgeois-nationalist revision of the Marxist-Leninist theory of the objective laws of historical development and at a reevaluation of the key periods in the history of Czechoslovakia and the workers' and communist movement. The overcoming of these harmful tendencies in the early 1970's was the crucial prerequisite for the further development of Czechoslovak historiography.

Czechoslovak historians are working with international scholarly organizations and with historians in the USSR and other socialist states. Such cooperation includes the formation of bilateral historical commissions, the joint publication of multivolume collections of documents, and collaboration on basic historical research.

The main centers of historical research, which also train scholars and teachers, are the universities in Prague, Bratislava, Brno, Olomouc, and Košice-Prešov, the Institute of Czechoslovak and World History of the Czechoslovak Academy of Sciences

(CSAS) in Prague, the History Institute of the Slovak Academy of Sciences (SAS) in Bratislava, the Czechoslovak-Soviet Institute of the CSAS in Prague, the Institute of European Socialist Countries of the SAS in Bratislava, and the Silesian Institute of the CSAS in Opava. Other major centers of historical research are the Institute of Ethnography and Folklore of the CSAS in Prague, the Ethnography Institute of the SAS in Bratislava, the Archaeology Institute of the CSAS in Prague, the Archaeology Institute of the CSAS in Brno, the Archaeology Institute of the SAS in Nitra, the Oriental Institute of the CSAS in Prague, the Institute of Military History in Prague, the Institute of Marxism-Leninism under the Central Committee of the Communist Party of Czechoslovakia in Prague, and the Institute of Marxism-Leninism under the Central Committee of the Communist Party of Slovakia in Bratislava.

The main history periodicals are *Sborník historický* (since 1953), *Slovanské historické studie* (since 1955), *Slovanské štúdie* (since 1957), *Slovenský národopis* (since 1953), *Numismatický sborník* (since 1953), *Historica* (since 1959), *Archaeologické rozhledy* (since 1949), *Archiv orientalní* (since 1929), *Byzantinoslavica* (since 1929), *Československý časopis historický* (since 1953), *Český lid* (since 1892), *Památky archaeologické* (since 1909), *Slezksý sborník* (since 1936), *Slovanský přehled* (since 1899), *Historické studie* (since 1955), *Časopis Národného muzea* (since 1827), *Časopis Matice moravské* (since 1869), *Historický časopis* (since 1953), *Historie a vojenství* (since 1952), and *Studia historia slovaca* (since 1963). A. Kh. Klevanskii

ECONOMICS. In the Czech lands and Slovakia the study of economics developed later than in the West European countries. An urgent need for economic study arose only in the 19th century, when the disintegration of feudal relations and the development of capitalism, more rapid in the Czech lands than in Slovakia, were accompanied by a national revival. The foundations of Czech bourgeois economic theory were laid by F. L. Rieger, who in the mid-19th century wrote the first significant works on political economy in Czech, translated several works by French economists, and undertook to work out a Czech economics terminology. Bourgeois political economy developed rapidly in the Czech lands in the second half of the 19th century. Its main objectives were to justify theoretically the necessity of developing capitalism and eradicating feudal vestiges and to find ways of vanquishing both the German bourgeoisie, Czech capital's main competitor on the domestic and foreign markets, and the growing labor movement. This social function was fulfilled by F. A. Brauner, J. Kaizl, A. Bráf, and J. Gruber. The German historical school and the Austrian school of vulgar political economy had a great influence on the development of bourgeois political economy in the Czech lands.

Marxist economic theory was somewhat slow to gain a following in the Czech lands and Slovakia. The first Marxist works in Czech and an incomplete Czech translation of Marx' *Das Kapital* were published only shortly before World War I. It was not until 1937 that a popular exposition of Marxist political economy was published, A. Kamenický's *Fundamentals of Marxist Economics*. This circumstance facilitated the dissemination of reformist and opportunist ideas in the Czechoslovak labor movement. Revisionist interpretations of Marxism, such as that of F. Modráček, gained currency.

After 1918 bourgeois political economy was supported by the ruling circles, who required an economic theory that would defend the interests of the national bourgeoisie. Such a defense was provided by V. Mildschuh, A. Rašín, C. Čechrák, A. Basch, C. Horáček, and J. Loevenstein in the Czech lands and by I. Karvaš and R. Briška in Slovakia. K. Engliš, a prominent bourgeois political economist of the interwar period, proposed a teleological method of economic analysis based on the psychology of the economic "subject," seeking thereby to prove the viability of the capitalist economic system. Most bourgeois Czechoslovak economists were indebted to this theory down to World War II. J. Macek, who was strongly influenced by Keynesianism, had a considerable impact on the formation of the reformist views of the right-wing Czechoslovak Social Democrats.

The events of 1948 opened up broad opportunities for basic and applied economic research. In the 1950's Czechoslovak economists focused on the socialist nationalization of industry, the formation of agricultural cooperatives, the industrialization of backward areas, the achievement of a high growth rate of socialist reproduction, and the creation of a system of planning. Right-wing revisionist views proliferated in Czechoslovak economics in the 1960's and were even put into practice by the end of the decade. The revisionists, whose leading exponent was O. Šik, tried to justify the need for "market socialism" in Czechoslovakia. In the early 1970's this point of view was subjected to a comprehensive in-depth Marxist critique.

Czechoslovak economists are studying the political economy of capitalism, the political economy of socialism, the history of economic theories, and problems relating to national economic planning, the management of the socialist economy, and the efficiency of the national economy. Other research fields include the economics of agriculture, distribution, pricing policy, finance, the application of mathematical methods to economics, the international division of labor, the economics of foreign trade, and socialist economic integration. Significant work in these fields has been done by F. Oliva, V. Kvěš, L. Rendoš, J. Bouška, L. Ler, J. Nikl, J. Kabrhel, J. Řezníček, and J. Brčák. Cooperation in economic research is steadily expanding among the economists of the COMECON countries.

The main economics centers are the School of Economics in Prague, the School of Economics in Bratislava, the Institute of Economics of the Czechoslovak Academy of Sciences, the Institute of Economics of the Slovak Academy of Sciences, the Scientific Research Institute for the Planning and Management of the National Economy, the Czechoslovak Scientific Research Institute of Labor, and the Scientific Research Institute of the Standard of Living.

The principal economics journals are *Politická ekonomie* (since 1953), *Ekonomický časopis* (since 1953), *Plánované hospodářství* (since 1948), *Statistika* (since 1962), *Finance a úver* (since 1951), *Moderní řízení* (since 1966), and *Zahranični obchod* (since 1946). The weekly *Hospodářské noviny* has been published since 1958.

J. Brčak and E. D. Matvievskaia

JURISPRUDENCE. Urban, ecclesiastical, and other types of law, as well as jurisprudence, were highly developed by the turn of the 14th century, especially in the Czech lands. This period saw the appearance of the first official and private codifications of customary law, the former exemplified by Václav II's mining code and the *Maiestas Carolina* and the latter by the Rožmberk Book (13th–14th centuries), written in Czech, the law book of Ondřej of Dubá (1400), also in Czech, and the law book of the scribe Jan of Brno (14th century), written in Latin. In the late 14th and early 15th centuries lively discussions of current political and legal problems were held within and outside the law faculty of the University of Prague, which had become a center for the training of experts in canon law. The best-known work on legal matters was written by Cornelius Viktorin z Všehrd at the turn of the 16th century. The law book written by Pavel Kristián of Koldín in 1579 became the basis for standardizing urban law throughout the Czech lands in the next century. Slovakia, ruled by Hungarian feudal lords, also produced some important legal works, generally written in German, Latin, or Czech. Especially noteworthy are the first and second Bratislava law books (15th and 16th centuries), the *Articuli communitatis* of Košice (1604), and the law book of Žilina (15th century).

Despite the Hapsburgs' policy of germanizing political life and forcibly imposing German law, the traditional Czech law and legal system hung on throughout the 17th and 18th centuries. Eighteenth-century works calling for a national revival championed Enlightenment ideas and natural law (J. V. Monse). Earlier, J. A. Komenský (Comenius) had expounded progressive ideas concerning the state and law.

In the late 18th and early 19th centuries Czech legal scholars, notably M. A. Voigt and J. Veith, devoted much attention to the history of the Czech state and law. The heightened interest in Czech legal history that was kindled by the Revolution of 1848 led to the publication of major works by K. Sladkovský, A. Štrobach, and F. L. Rieger and to the creation of a Czech legal terminology. Nevertheless, an official jurisprudence developed only in the 1860's in connection with the emergence of Czech bourgeois legal science. The foremost legal scholars of the latter half of the century were A. Randa, E. Ott (civil law),

J. Pražák (public law), A. Zucker, F. Storch (criminalistics), B. Rieger, and J. Čelakovský (history of the state and law). A Slovak legal terminology was formulated in the late 19th century by M. Mudroň, and a Slovak bourgeois legal science emerged in the early 20th century under the guidance of E. Stodola and A. Rath.

Positivism and normativism were the dominant schools in official jurisprudence in the early 20th century. Fascist theories gained a certain influence in the 1930's.

The establishment of people's rule in Czechoslovakia was followed by the creation of a Marxist-Leninist legal science, but not without a struggle against bourgeois, right-opportunist, and antisocialist views of the state and law, which became especially influential in 1968–69. Czechoslovak jurists have done outstanding work on the theory of the state and law, the constitutional development of the country, socialist popular representative institutions, international law, socialist comparative law, the methodology of legal science, and the criticism of bourgeois ideology. Important works have been published on legal history by V. Vaněček and L. Hubenák, on constitutional law by K. Laco, S. Zdobinský, and S. Matoušek, on administrative law by V. Delong, Z. Lukeš, and Z. Červený, on civil law and procedure by S. Luby, K. Čapek, and Z. Češka, on labor law by J. Bičovský, M. Kalenská, J. Kovařik, and J. Filo, on criminal law by L. Šubert, J. Pješčak, and V. Solnař, and on agricultural cooperative law by J. Suchánek, V. Fábry, and J. Vysokaj.

Legal research is conducted by the Institute of State and Law of the Czechoslovak Academy of Sciences, the Law Institute of the Slovak Academy of Sciences, the Institute of State Administration under the Presidium of the Federal Government, and the Criminology Institute under the Procurator General's Office of the CSSR. There are law faculties at the universities in Prague, Bratislava, Brno, and Košice.

The leading law journals are *Právník* (since 1861), *Právny obzor* (since 1917), *Socialistické soudnictví* (since 1961), *Správní právo* (since 1968), *Socialistická zákonnost* (since 1953), *Národný výbory* (since 1952), *Mezinárodní vztahy* (since 1966), and *Biulleten' chekho-slovatskogo prava* (since 1951). Also published are the yearbooks *Právněhistorické studie* (since 1955) and *Právnické studie* (since 1953). S. S. Novikova

LINGUISTICS. The first Czech grammars, written in Latin, appeared in the 16th century; the best known were those of B. Optát, P. Hzel, V. Filomat (1533), J. Blahoslav (1571), and M. Benešovský (1577). In the following two centuries Czech grammars were produced by B. Nudožerský, J. Drachovský (1600), V. J. Rosa (1672), P. Doležal (1746), and V. Pol (1756). The scientific study of Czech, as well as of other Slavic languages and non-Slavic languages, began in the late 18th and early 19th centuries, when J. Dobrovský produced the first scholarly grammar of Czech, and J. Jungmann published a five-volume Czech-German dictionary. Slovak was studied by A. Bernolák and L. Štúr, who is credited with founding the Slovak literary language. In the late 19th century the neogrammarian J. Gebauer wrote the *Historical Grammar of the Czech Language* (1894–1929) and the *Dictionary of Old Czech* (unfinished). Gebauer's ideas were further developed by V. Ertl and E. Smetánka. The linguist J. Zubatý studied the Indo-European languages, including the Baltic languages. After the establishment of the Czechoslovak republic in 1918, great strides were made in Slavic, Germanic, and Oriental philology. Using structural and functional research methods, the members of the Prague Linguistic Circle studied phonology, language culture, and the theory of literary languages and functional styles.

Highly favorable conditions for the development of linguistics have been created in the CSSR. Research in lexicology and lexicography has led to the publication of the *Dictionary of the Czech Language* (vols. 1–8, 1935–57), the *Dictionary of Literary Czech* (vols. 1–4, 1958–71), the *Dictionary of the Slovak Language* (vols. 1–6, 1959–68), the *Great Russian-Czech Dictionary* (1952–64), and the *Great Russian-Slovak Dictionary* (1960–70). Important work has been done on word formation (*Word Formation in the Czech Language*, vols. 1–2, 1962–67), morphology (*The Morphology of the Slovak Language*, 1966), and syntax. Transformational and generative grammar received much attention in the 1960's. Russian philology is flourishing; a notable achievement is the *Reference Grammar of the Rusian Language* (vols. 1–2, 1960–61). Other research fields include the theory of literary languages and their functional ramifications (B. Havránek, A. Jedlička, V. Barnet, J. Ružička, E. Paulíny), stylistics (K. Hausenblas, J. Mistrík), dialectology (B. Havránek), phonology (J. Vachek, E. Paulíny, A. Lamprecht), the history of language (M. Komárek, J. Stanislav, R. Krajčovič, K. Horálek, A. Novák), and general and comparative linguistics (K. Horálek). The English language has been studied on a high theoretical level by V. Mathesius, I. Poldauf, and J. Firbas. B. Hrozný made a vital contribution to Oriental philology.

The main linguistics centers are the Czech Language Institute (Prague), the L. Štúr Linguistics Institute (Bratislava), the special centers and institutes run by the Czechoslovak Academy of Sciences, and the philosophy and pedagogy faculties of universities. The principal linguistics journals are *Slovo a slovesnost* (since 1935), *Naše řeč* (since 1917), *Jazykovedný časopis* (since 1946), *Československá rusistika* (since 1956), *Philologica Pragensia* (since 1946), *Slavica Slovaca* (since 1966), *Archív orientální* (since 1969), and *Časopis pro moderní filologii* (since 1911). A. G. Shirokova

Scientific institutions. A coordinated state science program has been instituted in accordance with a 1949 law providing for the organization of research. Scientific, experimental, and design work is conducted by the Czechoslovak Academy of Sciences and the Slovak Academy of Sciences, by scientific and scientific-technological organizations subordinate to ministries and other central bodies, by scientific-technological institutions run by economic production organizations, by research and experimental sectors of enterprises, and by research divisions of higher educational institutions.

The central agencies responsible for administering, planning, and coordinating research are the State Committee for Science and Technology (the coordinating agency of the federal government), the federal Ministry of Technological and Investment Development, and the republic ministries of construction and technology. General policy is set by state programs for the development of science and technology. Research is conducted in cooperation with the COMECON countries.

In 1976 the country's research, design, and planning institutions employed 165,350 people, of whom 47,700 held advanced degrees. Some 24,000 people, including 10,400 with advanced degrees, were engaged in basic research (1974); 105,670 people, in industrial research (1976); 11,000 people, in agriculture and forestry research; 8,320 people, in public health research; 6,900 people, in construction research; and 2,520 people, in transportation and communications research. Expenditures on science amounted to more than 14.1 billion korunas in 1976.

Press, radio, and television

In 1978 there were 30 daily newspapers and 1,062 magazines with a total circulation of 21 million. The oldest and most influential dailies are the Czech-language *Rudé právo* (since 1920, circulation 900,000), the main organ of the Central Committee of the Communist Party of Czechoslovakia, and the Slovak-language *Pravda* (since 1920, circulation 330,000), published in Bratislava as the organ of the Central Committee of the Communist Party of Slovakia. The leading trade union press organs are *Práce* (since 1945, circulation 310,000), a Czech-language daily published in Prague by the Central Council of Trade Unions, and *Práca* (since 1946, circulation 190,000), a Slovak-language daily published in Bratislava by the Slovak Council of Trade Unions.

Two important newspapers are issued by ministries: *Obrana Lidu* (since 1942, circulation 200,000), a Czech-language weekly published in Prague by the Ministry of National Defense, and *Zemědělské noviny* (since 1945, circulation about 350,000), a Czech-language daily published in Prague by the Ministry of Agriculture and Food. The Czech-language daily *Mladá fronta* (since 1945, circulation 238,000), also published in Prague, is the main press organ of the Socialist Union of Youth.

The press organs of the noncommunist political parties are *Lidová demokracie* (since 1945, circulation, 217,000), a Czech-language daily published in Prague by the Czechoslovak People's Party; *Svobodné slovo* (since 1945, circulation 220,000), a daily Czech-language daily published in Prague by the Czechoslovak Socialist Party; and *Sloboda* (since 1946, circulation 6,000), a Slovak-language weekly published in Bratislava by the Slovak Freedom Party.

Among the leading magazines are the monthly *Nová mysl* (since 1947, circulation 40,000), the theoretical and political organ of the Central Committee of the Communist Party of Czechoslovakia; *Vlasta* (since 1947, circulation 800,000), a Czech-language weekly published in Prague by the Czech Women's Union; and *Slovenka* (since 1948, circulation 205,000), a Slovak-language weekly pictorial published in Bratislava by the Slovak Women's Union.

The Czechoslovak News Agency, founded in 1918, is located in Prague. Radio broadcasting, begun in 1923, is conducted in Czech and Slovak. Foreign broadcasts are made in Arabic, English, Hungarian, Spanish, Italian, German, Polish, Portuguese, Russian, Ukrainian, and French. Founded in 1953, the national television network consists of two systems, Program I and Program II, broadcasting from 34 television studios. Radio and television broadcasting are under the jurisdiction of Czechoslovak Radio and Czechoslovak Television, both government organizations.

I. N. LOBASHEVA

Literature

In view of the ethnic, linguistic, and historical affinity of the Czechs and Slovaks and their joint age-old struggle against foreign oppression, it was inevitable that their national literatures would develop through close contact and interaction, which were to become still stronger after the establishment of the Czechoslovak republic in 1918. (For the development of Czechoslovak literature prior to 1918, see CZECH SOCIALIST REPUBLIC and SLOVAKIA: Literature.) The upswing in the country's labor movement that took place under the impact of the Great October Socialist Revolution of 1917 in Russia inaugurated a new phase in Czech and Slovak literature marked by a flowering of revolutionary poetry, the exposé novel, the socialist realist novel, and antifascist literature.

Against the background of intensified class struggle, a revolutionary trend emerged in Czech and Slovak literature in the 1920's and 1930's, fostered by the Marxist writers and critics S. K. Neumann (1875–1947), J. Wolker (1900–24), J. Hora (1891–1945), Z. Nejedlý (1878–1962), B. Václavek (1897–1943), J. Fučík (1903–43), E. Urx (1903–42), V. Clementis (1902–52), and D. Okáli (born 1903). The press organs of the revolutionary trend were the magazines *Červen* (1918–21), *Kmen* (1917–22), and *Proletkult* (1922–24), all published by Neumann, and *Var* (1921–30), published by Nejedlý, as well as the culture section of the newspaper *Rudé právo*, founded in 1920. Proletarian literature was championed by Devětsil, an association of young Czech writers and artists founded in 1920, and Dav, an association of Slovak writers and critics formed in 1924.

Proletarian poetry reached a high level in the 1920's in the collections *Hour of Birth* (1922) by Wolker, *Red Songs* (1923) by Neumann, *A City in Tears* (1921) by J. Sejfert (born 1901), and *Sunday* (1927) by L. Novomeský (1904–76); the narrative poem *The Amazing Magician* (1922) by V. Nezval (1900–58); and the lyric poems of Hora, K. Biebl (1898–1951), and J. Poničan (1902–78). Revolutionary prose was best represented by the novels *The Good Soldier Švejk* (1921–23) by J. Hašek (1883–1923), *Anna the Proletarian* (1928) by I. Olbracht (1882–1952), *The Best of Worlds* (1923) by M. Majerová (1882–1967), and *The Baker Jan Marhoul* (1924) by V. Vančura (1891–1942). Also important were the works of P. Jilemnický (1901–49).

Critical realism flourished in the social novels of the Czech writers A. M. Tilschová (1873–1957), B. Klička (1897–1943), and K. Nový (born 1890). In the highly original novels and plays of K. Čapek (1890–1938) a scathing critique of many aspects of bourgeois society was blended with social utopianism and satire on philistinism. The leading Slovak realists were P. Hviezdoslav (1849–1921), M. Kukučín (1860–1928), B. Timrava (1867–1951), and J. Jesenský (1874–1945). The poets J. Smrek (born 1898) and E. B. Lukáč (born 1900) and the prose writer M. Urban (born 1904) called for an aesthetic and thematic renewal of literature.

Avant-garde trends such as Czech "poetism," expounded by K. Teige (1900–51), and idealist aesthetic theories became popular in the mid-1920's. Despite the pronouncements of the avant-garde writers, however, their finest achievement remained faithful to the tradition of revolutionary humanism, as exemplified by the works of Nezval, Vančura, and Biebl. A tragic view of the world, associated with the memory of the victims of World War I, and a protest against the capitalist world pervaded the poetry of V. Závada (born 1905), published in the collection *Requiem* (1927), and the verse of F. Halas (1901–49), collected in the volume *Sepia* (1927).

From the early 1930's the ideological and aesthetic polarization in literature was reinforced by the economic crisis, the mounting social conflict, and the fascist threat. The progressive intelligentsia formed a united front to combat clerical-nationalist and profascist tendencies. The most promising of the young proletarian poets who joined the literary scene were J. Noha (1908–66), J. Taufer (born 1911), F. Nechvátal (born 1905), and F. Král' (1903–55). The socioanalytical genre was cultivated by J. Kratochvíl (1885–1945), G. Včelička (1901–66), Urban, J. Cíger Hronský (1896–1960), M. Rázus (1888–1937), and G. Vámoš (1901–56); sociorevolutionary proletarian works were produced by Jilemnický, Král', and Poničan; and realist satire flourished in the works of Čapek, Jesenský, and the playwright I. Stodola (1888–1977). A sense of the discrepancy between humanist ideals and reality engendered a neoromantic trend in Slovak prose, best exemplified in the lyrical prose of D. Chrobák (1907–51), M. Figuli (born 1909), L. Ondrejov (1901–62), and F. Švantner (1912–50).

In the late 1920's and early 1930's the avant-garde theory of the autonomy of art was criticized by leftist writers. In their polemics with a group of Czech surrealists founded by Nezval in 1934 and disbanded by him in 1938, the Marxist critics Václavek, Fučík, K. Konrad (1908–41), L. Štoll (born 1902), Neumann, Novomeský, and Poničan developed the aesthetics of socialist realism, drawing on the discussions of the First Congress of Soviet Writers. The Alliance, which included both Czech and Slovak revolutionary writers, was founded in 1935 upon Václavek's initiative.

In the 1930's fine collections of civic and antifascist lyric poetry were published by Neumann, Závada (*The Road on Foot*, 1937), Halas (*Torso of Hope*, 1938), Hora, Lukáč (*Moloch*, 1938), and Novomeský (*A Saint Beyond the Outskirts*, 1939). Outstanding socialist realist novels included *The Untilled Field* (1932) by Jilemnický, *The Siren* (1935) by Majerová, *People at the Crossroads* (1937) by M. Pujmanová (1893–1958), *The Shoe Machine* (1933) by T. Svatopluk (1900–72), *Three Rivers* (1936) by Vančura, and *The Thorny Path* (1934) by Král'. Directed against fascism, Čapek's satirical philosophical novel *War With the Newts* (1936) and his plays *The White Plague* (1937) and *Mother* (1938) won international acclaim. On the initiative of Marxist critics and communist writers, a united cultural front was formed to combat fascism. At a writer's congress held in 1936, Slovak writers spoke out in defense of the republic and democracy.

The Nazi occupation of Czechoslovakia (1939–45) had a devastating impact on Czechoslovak literature. A number of writers, among them Vančura, Fučík, Konrad, Václavek, Kratochvíl, and Urx, perished in fascist prisons and camps. But cruel persecution did not throw the country's progressive literary forces into disarray. The theme of antifascist resistance dominated the poetry of Halas, Neumann, Závada, and Nezval, Vančura's literary chronicle *Scenes From the History of the Czech People* (vols. 1–3, 1939–40), and such underground Czech works as Fučík's *Notes From the Gallows*, published in 1945. The banned poems of Jesenský, Novomeský, Smrek, and Král' circulated in Slovakia. The Slovak people's resistance to the profascist regime was expressed

through symbol and allegory in Poničan's *Strange Janko* (1941), a heroic romantic poem about the Revolution of 1848, in Figuli's lyrical novella *The Lead Bird* (1940), and in Chrobák's lyrical novella *The Dragon Returns* (1943). A fervent antimilitarism marked many works by the Slovak surrealists R. Fabry (born 1915), V. Reisel (born 1919), P. Bunčák (born 1915), and J. Lenko (born 1914), as well as the poems of P. Horov (1914–1975). The wartime lyric poetry of Lukáč and V. Beniak (1894–1973) was imbued with a profound sense of tragedy.

After 1945 the struggle against fascism, the victory over the enemy, and gratitude to the Soviet liberators became the central theme in the poetry of F. Hrubín (1910–71), Nezval, V. Holan (born 1905), Halas, Jesenský, Král', A. Plávka (born 1907), Poničan, and M. Lajčiak (born 1926); the short stories of J. Drda (1915–70), notably his collection *The Silent Barricade* (1946); Jilemnický's novel *The Chronicle* (1947); and the prose of J. Marek (born 1914), J. Bodenek (born 1911), and J. Horák (1907–74). Nevertheless, some groups of bourgeois writers and literary critics continued to cling to their views. Communist writers assailed the resuscitated conceptions of "pure art" and tried to rally the progressive cultural figures around the Communist Party, a line of action that received wide support at the First Congress of Slovak Science and Art Workers, held in 1945, and at the 1946 congress of Czech writers.

The final rout of the bourgeoisie in February 1948 ushered in a new phase in the struggle for a socialist literature that clearly demonstrated the cohesion of the progressive Czech and Slovak literary forces. The Congress of National Culture, held in April 1948, resolved to promote the socialist orientation of literature. The First Congress of Czechoslovak Writers, convened in March 1949, formed the Czechoslovak Writers' Union, which adopted socialist realism as its program. The theory of socialist realism was elaborated by Nejedlý, Štoll, Taufer, J. Hájek (born 1919), and M. Chorváth (born 1910).

With the ascendancy of socialist realism in the 1950's, Czechoslovak writers showed a predilection for vast epic panoramas portraying crucial moments in the country's history. A Marxist interpretation of the historical destiny of the Czechs and Slovaks and their path to socialism was given in the last two volumes of Pujmanová's trilogy, *Playing With Fire* (1948) and *Life Against Death* (1952), in the chronicle novels *New Soldiers Will Arise* (1948), *The Turbulent Year 1905* (1949), and *The Red Glow Over Kladno* (1951) by A. Zápotocký (1884–1957), and in the novel *Red Wine* (1948) by F. Hečko (1905–60). The building of a new life was depicted in the novels *The Offensive* (1951) and *The Battle* (1954) by V. Řezáč (1901–56), *Without a Chief* (1953) by Svatopluk, *The Peasant* (vols. 1–2, 1955–58) by B. Říha (born 1907), *Yesterday and Tomorrow* (1949) by V. Mináč (born 1922), *The Wooden Village* (1951) by Hečko, and *The Wasps' Nest* (1953) by K. Lazarová (born 1914). Nezval's new works, notably the narrative poem *Song of Peace* (1950), gained world renown. Some of the best poetry of these years was written by Závada, Hrubín, J. Kainar (1917–71), J. Kostra (1910–75), Horov, V. Mihálik (born 1926), and S. Žary (born 1918).

An imperfect mastery of the theme of socialist construction sometimes resulted in a superficial and hackneyed treatment of industrial themes in prose, sloganeering in poetry, and oversimplification in criticism. From the mid-1950's the normative antiartistic trends were combated by writers who sought to show the full complexity and the contradictory nature of the modern historical process and contemporary developments. Especially successful in this respect were the novels *Citizen Brych* (1955) by J. Otčenášek (born 1924), *If You Leave Me* (1957) by Z. Pluhař (born 1913), and *Box for the Living* (1956) by N. Frýd (1913–76) and the short-story collection *Hours and Minutes* (1956) by A. Bednár (born 1914). Outstanding achievements of socialist realism in Slovak literature included the trilogy *A Generation* (parts 1–3, 1958–61) by Mináč, the novel *The Dead Don't Sing* (1961) by R. Jašík (1919–60), the lyric and narrative poems of Novomeský, and the poetry of Kainar and M. Válek (born 1927).

Nihilist tendencies grew stronger in the mid-1960's, not infrequently turning into a rejection of socialism, and some writers succumbed to the influence of Western modernism, principally the "new novel," the theater of the absurd, and "concrete" poetry. The literary magazines published articles propounding reactionary-modernist, neo-avant-garde, and structuralist theories. During the political crisis of 1968 the Czechoslovak Writers' Union, whose leadership had adopted revisionist views, virtually ceased to exist as a creative organization. "An outright capitulation to bourgeois ideology . . . could be observed in the field of culture and art" (*Uroki krizisnogo razvitiia*, Moscow, 1971, p. 41). After the April 1969 Plenum of the Central Committee of the Communist Party of Czechoslovakia, a campaign was launched to overcome the consequences of the crisis in ideology, culture, and literature. The Slovak Writers' Union, founded in 1969, and the Czech Writers' Union, established three years later, lent their full support to the party's political and cultural line and set as their primary task the unification of the country's literary forces on the basis of socialist realism.

In the early 1970's continuity was restored with the best traditions of the preceding period. Socialist poetry has been further developed by Závada, Plávka, J. Rybák (born 1904), Taufer, I. Skála (born 1922), Mihálik, M. Florian (born 1931), M. Rúfus (born 1928), J. Mihalkovič (born 1935), and V. Hons (born 1938). Fine historical novels have been written by Říha, M. V. Kratochvíl (born 1904), J. Toman (1899–1977), V. Neff (born 1909), and H. Zelinová (born 1914). The memoir and historical essay genres are best represented by Plávka's *In Love With Life* (1971) and Mináč's *Fanning the Native Hearths* (1970) and *J. M. Hurban's Quarrels* (1974). The antifascist theme is explored in a number of fine novellas and novels: *Wildings* (1973) by J. Křenek (born 1933), *One Piece of Silver* (1974) by Pluhař, *Love the Time That Will Come* (1974) by J. Papp (born 1929), *The Cedar Grove* (1974) by V. Švenková (born 1937), *Hearths* (1976) by E. Dzvoník (born 1933), and *Craftsmen* (1976) by V. Šikula (born 1936).

Contemporary ethical and social issues are raised in the novel *My Boy and I* (1974) by J. Kolárová (born 1919) and in the novels *St. Michael* (1971), *The White Stallion* (1975), and *The Stork's Nest* (1976) by J. Kozák (born 1921). The novel *Little Shepherd From the Valley* (1977) by L. Fuks (born 1923) describes, in a lyrical vein, the new life in the Czechoslovak countryside after 1945. The novel *The Eleventh Commandment* (1975) by J. Jonáš (born 1919) deals with the socialist transformation of the Slovak village. The production theme lies at the heart of the novellas *Hardships of the Plains* (1975) and *Salty Snow* (1976) by M. Rafaj (born 1934) and the novel *The Breakdown* (1976) by J. Švejda (born 1950). A fresh ideological and aesthetic approach to the treatment of socialist reality distinguishes the prose of P. Jaroš (born 1940), I. Habaj (born 1943), L. Ballek (born 1941), V. Klevis (born 1933), J. Navrátil (born 1939), J. Kostrhun (born 1942), and L. Štěpán (born 1943). A noteworthy contribution to modern dramaturgy has been made by I. Bukovčan (1921–75), J. Solovič (born 1934), and O. Zahradnik (born 1932).

The Czechoslovak Writers' Union was revived in December 1977.

Literary scholarship. A number of conflicting trends coexisted in literary criticism in the interwar period. While A. Novák (1880–1939) elucidated the history of Czech literature from the standpoint of official bourgeois ideology, A. Pražák (1880–1956) applied the positivist methodology and J. Mukařovský (1891–1975) and M. Bakoš (1914–72) developed the idea of literary structuralism. The general democratic trend was represented by F. X. Šalda (1867–1937), Š. Krčméry (1892–1955), and F. Votruba (1880–1953). Z. Nejedlý played a major role in the development of the Marxist school. A significant contribution to the Marxist methodology of literary scholarship and to the scholarly study of the history of Czechoslovak literature was made by the Marxist critics of the 1920's and 1930's, notably B. Václavek, the author of *Twentieth-century Czech Literature* (1935).

A general shift toward a Marxist reorientation of literary scholarship began after 1948. Novák's theories were criticized, and Mukařovský and Bakoš gave a critique of the idealist principles of structuralism. Among the newly founded centers of literary scholarship were the Czech and World Literature Institute of the Czechoslovak Academy of Sciences in Prague and the Literature Institute of the Slovak Academy of Sciences in Bratislava. Literary scholars began working on an academic history of Czech and Slovak literature and on Czechoslovak-Soviet literary relations. Structuralist and other idealist theories were resurrected in the

1960's. In overcoming the consequences of the crisis, the positions of Marxist aesthetics and methodology were strengthened.

Of the older generation of Marxist critics, Štoll, Taufer, V. Pekárek (born 1907), and A. Matuška (1910–75) continued to publish prolifically in the 1970's. The leading younger Marxist critics were S. Šabouk (born 1933), V. Dostál (1930–75), H. Hrzalová (born 1929), Š. Vlašín (born 1924), and V. Rzounek (born 1921) in the Czech lands and K. Rosenbaum (born 1920), I. Kusy (born 1921), S. Šmatlák (born 1925), M. Tomčík (born 1922), and J. Števček (born 1929) in Slovakia. A valuable contribution to the elucidation of the history of Czechoslovak literature was made by A. Mráz (1904–64), J. Hrabák (born 1912), and M. Pišút (born 1908).

The main literary journals are *Česká literatura* (since 1953), *Slovenská literatúra* (since 1954), *Literárni měsičník* (since 1972), *Romboid* (since 1965), and *Slovenské pohľady* (since 1884).

Architecture and art

The architecture, fine art, and decorative applied art of Czechoslovakia have developed out of the artistic traditions of the Czech lands and Slovakia, which maintained close cultural ties from early times (*see* CZECH SOCIALIST REPUBLIC and SLOVAKIA: Architecture and art). The establishment of an independent Czechoslovak state in 1918 stimulated a cultural revival in the two historical regions and contributed to their further rapprochement. In the 1920's and 1930's Czechoslovak art was strongly influenced by the Great October Socialist Revolution of 1917, by the short-lived Hungarian and Slovak soviet republics (1919), and by the growth of the communist and labor movements. Under the bourgeois regime the development of artistic culture was marked by contradiction. Democratic and socially critical tendencies and quests for an indigenous style coexisted with borrowings from European avant-garde currents. A progressive national trend arose and matured in the struggle against modernist tendencies.

In the architecture of the 1920's and 1930's neoclassicism, popular for a short time, gave way to a national school of functionalism, best represented by the buildings of J. Gočár, K. Honzík, and J. Havlíček in the Czech lands and E. Belluš in Slovakia. Along with industrial enterprises, the first housing projects were built using standard designs and industrial construction methods. A rational layout of residential ensembles was attempted at Zlín (now Gottwaldov) and in parts of Bratislava and Košice. However, housing construction was limited in the interwar period, and slums proliferated on the outskirts of cities.

The art of the 1920's and 1930's was characterized by a strengthening of realist and democratic tendencies. Artists of different schools portrayed the life of the people and contemporary reality employing cubist, expressionist, and fauvist techniques. In the Czech lands such an approach was typical of the painting and graphic art of V. Beneš, J. Čapek, V. Rabas, and R. Kremlička and the sculpture of O. Gutfreund. In Slovakia it was represented by the painting and graphic art of M. Benka, M. A. Bazovský, J. Aleksy, and M. Galanda. Some artists were influenced by folk art techniques, as may be seen from the graphic art of J. Čapek and J. Lada in the Czech lands and the paintings of L. Fulla in Slovakia. The national realist traditions of the late 19th and early 20th centuries retained their vigor in the landscapes of V. Rabas, V. Sedláček, and V. Novák, the engravings of M. Švabinský, the illustrations of V. Brunner and F. Kysela, and the portraits and statues of K. Kotrba, K. Pokorný, and J. Lauda, all of them Czech artists.

A critical view of society united the painters K. Holan and P. Kotík and the graphic artists V. Silovský and J. Rambousek, who formed yet another school in the 1920's. The Devětsil association of revolutionary artists, founded in 1920, dedicated itself to the creation of a proletarian art. The artistic aspirations of its members, however, were somewhat inconsistent. The life of the working class was depicted in the 1920's by the Czech graphic artists V. Mašek and F. Bidlo, by the Slovak graphic artist K. Sokol, and by the Slovak painter K. Bauer.

Confronted with the fascist threat, artists of various schools formed a united antifascist front. Some of the best political graphic art was produced by the Czech artists Bidlo and J. Čapek. In the late 1930's and early 1940's a dramatic intensity and at times a heroic quality infused the antiwar compositions and pictures showing the resistance and sufferings of the people of Czechoslovakia under fascist occupation. These themes received eloquent treatment in the works of V. Sychra and V. Tittelbach in the Czech lands and of V. Hložník, J. Želibský, J. Nemčík, and C. Majerník in Slovakia. A number of artists had recourse to allegory and disguised imagery. The homeland theme took on political overtones in the landscapes and peasant scenes of the Czech artists V. Rabas, V. Rada, and B. Dvorský.

The liberation of Czechoslovakia from fascist occupation in 1945 and the establishment of a people's democratic system opened the way for the unfettered development of the finest traditions of the democratic national culture. Large modern industrial enterprises such as the metallurgical combine in Košice were built, as well as dams and hydroelectric power plants on the Labe, Vltava, and Orava rivers. New industrial cities, among them Mladá Boleslav, Ostrava-Poruba, and Havířov, were founded. Comfortable residential quarters were built employing industrial techniques on the outskirts of Prague, Bratislava, Gottwaldov, Olomouc, Nitra, Košice, and other cities. Examples of well-designed public buildings and transportation facilities include the Institute of Macromolecular Chemistry and the Federal Assembly Building in Prague, the agricultural institute and student dormitories in Nitra, and the Bridge of the Slovak National Uprising in Bratislava.

The prewar realist traditions remained strong in art in the late 1940's and early 1950's. The works of many artists held a new, socialist message. Industrial landscapes and compositions depicting labor and the national liberation struggle were created by the Czech painters and graphic artists E. Filla, J. Brož, and V. Sedláček and by the Slovak artists V. Hložník, O. Dubay, R. Dúbravec, J. Želibský, and B. Hoffstädter. Among Czech artists, M. Švabinský revived portrait graphic art; J. Lauda, K. Lidický, and K. Hladík produced outstanding sculpture; and J. Slavíček, B. Dvorský, and F. Jiroudek excelled in landscape painting. In Slovakia, the painters J. Aleksy, M. Bazovský, and L. Fulla and the graphic artists V. Chmel and M. Čechová evoked poetic generalized scenes from the life of the people.

Monumental decorative art reached a high level in the Czech lands in V. Sychra's mosaics, A. Zábranský's sgraffito, and V. Tittelbach's frescoes. There were impressive achievements in decorative applied art, notably glass-making, weaving, pottery, and medallion-making. Splendid memorial complexes commemorating the World War II victory and honoring those who died fighting against fascism were created by V. Makovský, K. Lidický, and K. Pokorný in the Czech lands and by J. Kulich, T. Bártfay, and J. Kostka in Slovakia. Fine book illustrations were produced by C. Bouda, Zábranský, A. Pelc, K. Svolinský, and A. Strnadel in the Czech lands and by V. Hložník and L. Fulla in Slovakia.

From the late 1950's a number of artists showed a growing interest in symbolic and poetic imagery and formal experimentation. The actions of antisocialist elements in the late 1960's had a pernicious effect on the development of Czechoslovak art. Such Western modernist trends as expressionism, neocubism, surrealism, abstractionism, and op art attracted a large following. Since the early 1970's strong efforts have been made to restore the democratic traditions of Czechoslovak art. Monuments commemorating national historical events and the liberation and revolutionary struggle have been executed by J. Kulich, T. Bártfay, and J. Kuzma in Slovakia and by M. Hana, V. Dobrovolný, J. Malejovský, and J. Simota in the Czech lands. The history of the revolution has been recorded in the canvases of the Czech artists Zábranský, K. Souček, and R. Kolář.

Music

Czechoslovak music is rooted in the musical traditions of the Czech lands and Slovakia, which evolved through mutual influence (*see* CZECH SOCIALIST REPUBLIC and SLOVAKIA: Music). After the establishment of an independent Czechoslovak state in 1918, strong efforts were made to preserve and develop the realist traditions of the national classics, but the bourgeois leadership's orientation toward West European culture facilitated the penetration of modernist trends into Czechoslovak music. The Society for Modern Music and the Přítomnost Society were founded in 1920. A. Hába, a leading Czech avant-garde composer of the 1920's and 1930's, invented the quarter-tone and the sixth-tone systems of music.

Concurrently, the foremost composers of the older generation, notably L. Janáček, J. B. Foerster, V. Novák, and J. Suk, who were also the leading teachers, continued to develop the realist national traditions. In his scholarly publications and public activity the eminent man of letters Z. Nejedlý championed the artistic principles of the Czech classics and called for closer cultural ties with the USSR. He was a cofounder of several societies dedicated to promoting a cultural rapprochement between Czechoslovakia and the Soviet Union. A number of progressive musicians rallied around Nejedlý, among them O. Ostrčil, V. Helfert, O. Jeremiáš, and E. Axman. As the conductor and artistic director of the opera company of the National Theater in Prague from 1923 to 1931, Ostrčil staged operas by B. Smetana, Z. Fibich, A. Dvořák, Foerster, Novák, and Janáček.

Instrumental works from the national repertoire were frequently performed by the orchestra of the Czech Philharmonic Society (founded in 1894 and directed by V. Talich from 1919 to 1931 and from 1934 to 1941), the Czech Quartet (founed 1891), the Ševčik Quartet (1900), the Prague Quartet (1920), the Ondříček Quartet (1928), the Prague Wind Quintet (1928), and the Czech Nonet (1924).

The 19th-century composers who founded professional Slovak music, namely J. L. Bella, V. Figuš-Bystrý, M. Schneider-Trnavský, and M. Moyzes, were strongly influenced by the national folk music. Their musical legacy was further developed in the 20th century by Novák and his students E. Suchoň, J. Cikker, and A. Moyzes. Among the finest Slovak compositions of the 1930's were Cikker's orchestral works and Suchoň's Symphony No. 2, his orchestral suite *Down the Váh*, his program overtures, and his cantata *Psalm of the Sub-Carpathian Land*. The most important of the Slovak musical performing groups and organizations that were founded in the interwar period were the Zora Chorus (1919), the Radio Instrumental Ensemble (1928), the opera company of the Slovak National Theater (1920), and the Music School, founded in 1919 and reorganized as an academy of music and drama in 1928 and as a conservatory in 1941.

Many works from the 1930's were devoted to the revolutionary struggle of the working class, among them V. Nejedlý's Second and Third symphonies, J. Stanislav's *Song About Granada*, and E. Schulhoff's cantata *The Communist Manifesto*. The music section of the League of Czechoslovak Friends of the Theater maintained ties with workers' organizations and with the Communist Party of Czechoslovakia. The composer and conductor E. F. Burian, who founded the D-34 Theater in 1933, affirmed that art should serve the working class. Ostrčil's opera *Honza's Kingdom* (1934) developed the antifascist theme.

Patriotic works were composed during the fascist occupation in World War II. Among the most famous were O. Chlubna's *Jiří of Kunštát and Poděbrady*, E. Schulhoff's *Symphony of Freedom* (1941), J. Stanislav's *Red Army Symphony*, J. Hanuš's opera *The Flames*, K. Horký's opera *Jan Hus*, O. Jeremiáš's cantata *Song of the Native Land*, Novak's cantata *St. Wenceslas Triptych*, and B. Martinů's play for orchestra *Memorial to Lidice* (1943) and his Symphony No. 3 (1944). Many composers masked their musical ideas, using cryptograms, allegories, and citations from widely known national patriotic works, such as the Hussite songs. Performers included in their programs revolutionary and humanistic classic works. The Slovak musicians J. Cikker, J. Kresánek, and T. Andrašovan fought in the resistance movement. Among the many progressive musicians who died during the occupation were R. Karel, J. Teklý, E. Schulhoff, G. Klein, and P. Haas.

After the victory over fascism in 1945 and the establishment of a people's democratic system in Czechoslovakia, composers' associations, first Czech and then Slovak, were founded, and a new opera theater, called the May 5 Great Opera, was opened (it merged with the National Theater in 1948). In 1946 the Academy of Arts was founded, higher music schools were opened in Bratislava and Brno, and the international festival Prague Spring was inaugurated. The music of the second half of the 1940's reflects the general revival throughout the country. A feeling of optimism pervades V. Novák's *May Symphony*, J. Seidel's cantata *1945* and his cantata triptych *The Heritage of Julius Fučík*, A. Očenáš's symphonic trilogy *Resurrection*, and J. Cikker's symphonic poems *About Life* and *Morning*.

The victory over bourgeois reaction in 1948 and the onset of socialist construction stimulated a flowering of democratic music. The Czechoslovak Composers' Union was organized in 1949 through a merger of the associations of Czech and Slovak composers. The works of the 1950's were inspired by the building of a new life and glorified free labor and peace on earth, themes that were most fully developed in cantatas and mass songs. Outstanding vocal compositions included V. Dobiáš's cantata *Build Up the Motherland and You Will Strengthen Peace!* and his mass song *Join our Brigade*, J. Stanislav's songs, and J. Seidel's oratorio-cantata *People, Be Vigilant!* and songs. Z. Nejedlý's speeches and articles, notably his "On True Realism and Pseudorealism" (1948) and "Learn to Speak Through Music," were of great ideological importance because they helped to overcome the contradictions between artistic truth and a narrowly conceived populism that had manifested themselves in the works of some Czech and Slovak composers.

In the late 1940's and in the 1950's musical theaters in Czechoslovakia and other countries performed works by Czech and Slovak composers: P. Bořkovec's opera *Paleček* (1947), J. Doubrava's ballet *Don Quixote* (1955), E. Suchoň's operas *The Whirlpool* (or *The Whirlwind*, 1949) and *Svatopluk* (1959), and J. Cikker's *Jánošík* (1953), *Beg Bajazid* (1956), and *Mr. Scrooge* (after Dickens, 1958). Instrumental music was written by J. Řídký, who produced seven symphonies and numerous chamber works, I. Krejčí, and Dobiáš. European music was enriched by the compositions of B. Martinů, who worked in many genres and styles. Although he lived abroad for a long time, Martinů never lost touch with his homeland and made a major contribution to Czechoslovak music. In all, he composed about 400 works, including the operas *Juliette* (1937), *The Marriage* (based on Gogol's play, written for television, 1952), *Mirandolina* (1954), *Greek Passion* (1958), and *Ariadne* (1958); the ballets *Revolt* (1925), *The Judgment of Paris* (1935), and *The Strangler* (1948); and six symphonies.

Among outstanding Czech works produced since the late 1950's are J. Pauer's opera *Zuzana Vojířová* (1959), S. Havelka's Symphony No. 1, V. Sommer's *Vocal Symphony*, V. Kalabis' *Symphony of Peace*, and J. Válek's *Renaissance Symphony* and *Revolutionary Symphony*. Important works have also been written by L. Železný, O. Flosman, J. Boháč, I. Irko, V. Felix, and J. Matěj. Fine Slovak works of this period include Cikker's operas *Resurrection* (1961), *A Play About Love and Death* (1968), and *Coriolanus* (1973), T. Frešo's opera *Martin and the Sun*

(1972), Cikker's *Symphony 1945* (1975), and various works by Suchoň, A. Očenáš, and D. Kardoš.

Since the 1950's operatic art has been fostered by the opening of several opera theaters in Bohemia, Moravia (1954), and Slovakia. The country's musical life has been enriched by the founding of symphony and chamber orchestras, choral groups, string quartets, including the Smetana and Janáček quartets, the Suk Trio, the ensemble of the Czechoslovak People's Army, such song and dance ensembles as the Czechoslovak Song and Dance Ensemble and the Slovak SLUK and Lúčnica ensembles, and various amateur groups.

Czechoslovakia has produced many distinguished performing musicians, among them the conductors V. Neumann, V. Smetáček, J. Krombholc, and L. Slovák, the pianists I. Moravec and J. Páleníček, the harpsichordist Z. Růžičková, the organists J. Reinberger and J. Ropek, the violinists A. Plocek and J. Suk, the cellists I. Večtomov, M. Sádlo, and J. Chuchro, the female singers M. Tauberová, V. Soukupová, and G. Benjačková, and the male singers B. Blachut, I. Žídek, V. Bednář, and E. Haken.

The leading music journals are the Czech-language *Hudba a škola* (1928–33, 1940, and since 1960), *Hudební rozhledy* (since 1948), and *Hudební věda* (since 1964) and the Slovak-language *Hudobnovedné študie* (since 1955), *Slovenská hudba* (1957–71), and *Hudobný život* (since 1966).

Ballet

After the formation of the bourgeois Czechoslovak republic in 1918, the first ballet companies were established in Bratislava, Brno, Ostrava, and Olomouc, supplementing the company already existing in Prague, and private ballet schools were opened. The ballet repertoire began to include works by Czech composers, such as B. Martinů's *Istar* (1924, National Theater in Prague) and *Who Is the Most Powerful in the World?* (1925, Brno ballet company) and V. Novak's *Nikotina* (1930) and *Signorina Gioventù* (1930; both performed at the National Theater in Prague). The leading Czech dancers and choreographers of the interwar period were J. Jenčík and I. V. Psota.

Soon after the liberation of the country from the fascist German aggressors in 1945, ballet theaters were opened in Plzeň, Opava, Košice, České Budějovice, Kladno, and Ustí nad Labem. In 1946 choreography departments were formed at the conservatories in Prague, Bratislava, and Brno, and three years later a subdepartment of choreography theory and history was established at the Academy of Arts in Prague. The company attached to the National Theater in Prague was directed by S. Machov (1946–51) and the company of the Janáček Opera and Ballet Theater in Brno by Psota (1947–51).

Czechoslovak ballet is characterized by realism, precise dramatic rendering of the scenario, and highly expressive performing technique. The stylistic versatility and sophisticated stage design of postwar ballet were splendidly revealed in the productions of Z. Vostřák's *A Philosophical Story* (after A. Jirásek, 1949, stage designer V. Fridrichova) and his *Viktorka* (based on B. Němcová's *Grandmother*, 1950, stage designers Z. Rossmann and K. Kropáček), both choreographed by Machov and J. Reimoser. Among the National Theater's finest productions were the *Slavonic Dances*, based on the music of A. Dvořák (1956), A. I. Khachaturian's *Spartacus* (1957), A. D. Melikov's *Legend of Love* (1963), and S. S. Prokofiev's *Romeo and Juliet* (1976). The theater's leading dancers are O. Skálová, M. Kůra (appointed director of the National Theater's company in the mid-1970's), M. Drottnerová, M. Pešíková, and V. Harapes. The foremost choreographers are A. Landa, J. Blažek, J. Němeček (the company's director from 1957 to 1970), and E. Gabzdyl.

The Slovak National Theater in Bratislava, another excellent company, has given memorable performances of R. M. Glière's *The Red Poppy* (1954), J. Kenessey's *The Kerchief* (1955), I. F. Stravinsky's *The Rite of Spring* (1964), and the *Heroic Trilogy* (1975), based on the music of various composers. The company's soloists include G. Starostová, G. Herényiová, V. Kolárová, and J. P. Plavnik, and its principal choreographers are J. Zajko and B. Slovák, who has directed the company since 1973.

The repertoire of the Janáček Opera and Ballet Theater in Brno has included Prokofiev's *Romeo and Juliet* (1938), Dvořák's *Slavonic Dances* (1951), Z. Křížek's *Ballad of a Sailor* (1961), and J. Hanuš' *Othello* (1974). The company's leading dancers are V. Vágnerová, K. Gracerová, and J. Bařinková; Němeček has served as its director since 1974. The New Ballet of Prague, which gave performances from 1964 to 1970 under the direction of the choreographer L. Ogoun and P. Šmok, introduced new dance forms and means of expression. The company toured the USSR from 1965 to 1969 and in 1970.

Theater

The Czechoslovak theater has developed the theatrical traditions of the Czech lands and Slovakia (*see* CZECH SOCIALIST REPUBLIC and SLOVAKIA: Theater). After the establishment of a bourgeois state in 1918, the theater reflected the various periods of the country's bitter class struggle. In addition to the National Theater and Vinohrady Theater in Prague and the National Theater in Brno and Plzeň, the country now had several new major theaters: the Municipal Theater in Brno (1919), the Slovak National Theater in Bratislava (1920), and the Municipal Theater in Olomouc (1920). Amateur drama groups sprang up throughout the country. The communist critics J. Fučík, M. Majerová, K. Konrád, B. Václavek, and Z. Nejedlý made a vital contribution to public life and the theater. Progressive directors staged antibourgeois plays preaching humanitarian values and progress.

The National Theater in Prague gave outstanding performances of K. Čapek's *The Insect Comedy* (1922) and *The White Plague* (1937), F. X. Šalda's *The Child* (1930), and Shakespeare's *Romeo and Juliet* (1924), *Hamlet* (1930), and *Julius Caesar* (1936). The Vinohrady Theater staged plays by F. Wedekind, J. Hilbert, and P. Claudel, as well as E. Verhaeren's *Dawn* (1920), A. Dvořák's *The Hussites* (1920), K. Čapek's *The Macropoulos Secret* (1922 and 1927), and Goethe's *Faust* (1932). One of the most successful of the new professional and semiprofessional revolutionary theaters was the Liberated Theater, organized in 1925. Its director, J. Honzl, staged antibourgeois political reviews written and performed by the actors J. Voskovec and J. Werich, with music provided by the composer J. Ježek. At the D-34 Theater, a revolutionary theater founded in 1933, E. F. Burian sought to popularize the principles of the proletarian theater and to learn from the experience of the Soviet theater. An acting style emerged that combined subtle psychological portrayal with close attention to external characterization. Its most gifted exponents were V. Vydra, Z. Baldová, J. Průcha, L. Dostálová, O. Scheinpflugová, and Ž. Štěpánek.

A Slovak school of acting arose in the 1920's under the guidance of J. Borodáč, A. Bagar, and O. Borodáčová-Orszaghová. The Czech stage directors V. Šulc and J. Jamnický were instrumental in developing a Slovak school of directing. Among the finest productions of the Slovak National Theater in the 1930's were J. G. Tajovský's *Confusion*, J. Palárik's *An Adventure at the Harvest Home*, J. Záborský's *The Foundling*, P. Hviezdoslav's *Herod and Herodias*, and M. Gorky's *Lower Depths*.

The development of Czech directing owed much to the young newcomers J. Frejka and O. Stibor. The art of stage design was also perfected, becoming an important element in the productions of V. Hoffmann, F. Troester, F. Kysela, and F. Zelenka.

During the fascist occupation (1939–45) the country's theater companies lost many members, and the repertoire was strictly censored. The progressive men and women of the theater resisted fascism, founding semiprofessional studios, of which Honzl's Theatricum for 99 was the best known. In its productions of F. Schiller's *Wilhelm Tell* and P. Zvon's *A Dance Over Crying*, the Slovak National Theater conveyed the people's protest against the fascist regime. The Chamber Theater in Martin, founded in 1944, became a frontline theater after the outbreak of the Slovak national uprising in August 1944; the next year it was renamed the Theater of the Slovak National Uprising.

After the liberation of Czechoslovakia from fascist occupation, Czech and Slovak theaters participated in the creation of a socialist culture. Private theaters were abolished, a theater law was enacted in 1948, and new performing groups were founded for the ideological and political education of the working people, among them the Realist Theater (later named in honor of Z. Nejedlý) in Prague, the Workers' Theater in Gottwaldov, and the Disk theater workshop. The D-34 Theater staged the first play on the theme of labor, V. Káňa's *Grinder Karhan's Worker Team* (1949), and the S. K. Neumann Theater's production of M. Stehlík's *Village Love* for the first time brought to the stage the acute class struggle in the country. The Union of Creative Theater Workers, founded in 1957, functioned with interruptions until 1972, when it was reorganized as the Union of Creative Theater, Cinema, and Television Workers.

The fine realistic performances of the middle generation of Czech actors and actresses, notably J. Petrovická, J. Švorcová, V. Matulová, J. Větrovec, V. Vejražka, M. Růžek, V. Vlasková, and B. Holišová, demonstrate their mastery of the traditions of the Czech acting school developed by the distinguished stage veterans Průcha, Štěpánek, Dostálová, L. Pešek, B. Záhorský, V. Šmeral, K. Höger, J. Dohnal, S. Amortová, F. Smolík, and J. Kurandová. A major contribution to the art of directing has been made by K. Palouš, M. Macháček, and Z. Míka. In addition to the older theater companies, there are a number of highly successful theaters of miniatures: the Zábradlí (Balustrade), Semafor, Činoherní Klub, and Rococo, all founded in Prague in the late 1950's, and Na Provázku (On the Rope, Brno) and Epsilon (Liberec), both established in the 1970's. Czechoslovak stage design has achieved a high reputation through the work of J. Svoboda, V. Šimáček, and Z. Kolář.

The Slovak National Theater, now one of the country's leading companies, has had a strong impact on the development of the artistic culture of the CSSR. Other major Slovak theaters include the New Stage and the Poetic Stage in Bratislava, the Tajovský Theater in Banská Bystrica and Zvolen, the State Theater in Košice, and the Záborský Theater in Prešov. The most popular of the theaters serving national minorities are the Ukrainian National Theater in Prešov and the Hungarian Regional Theater in Komárno. The foremost Slovak stage directors are J. Budský, P. Haspra, P. Mikulik, and T. Rakovský. L. Vychodil, the principal stage designer of the Slovak National Theater, is credited with founding a national school of stage design. The work of the stage designers M. Hložek and V. Suchánek has also won acclaim. The leading Slovak performers are O. Borodáčová-Orszaghová, M. Prechovska, M. Královičová, N. Hejna, Z. Grúberová, V. Strnisková, B. Turzonová, E. Vášaryová, and M. Huba.

Among the finest productions of the 1970's were V. V. Vishnevskii's *An Optimistic Tragedy* (Drama Theater, Ostrava), J. Solovič's *Meridian* and O. Zahradnik's *Solo for a Striking Clock* (both at the Slovak National Theater, Bratislava), A. Mrštík and V. Mrštík's *Maryša*, I. M. Dvoretskii's *The Stranger*, M. Gorky's *Smug Citizens*, V. Nezval's *Lovers From a Kiosk* (all at the National Theater, Prague), and N. Jirsíková's *May* (Burian Theater, Prague).

Theater artists are trained at the Academy of Arts in Prague and at the Higher Theatrical School in Bratislava. The principal theater magazines are the Slovak *Slovenské divadlo* (since 1953) and the Czech *Amaterska scena* (since 1955). The weekly *Scena*, founded in 1976, focuses on current developments in the Czech theater, cinema, and television.

Circus. Having come into being at the turn of the 20th century, the professional Czechoslovak circus was developed in the interwar period by the troupes of E. Beránek, Š. Slezák, and K. Kludský, the son of A. V. Kludský, who founded a circus dynasty. In 1951 private circuses were nationalized. The Circus Center, founded in Prague in 1961, has two arenas and various auxiliary buildings for preparing new and perfecting old numbers. In addition, there are three tent circuses: the Prague, the International, and the Umberto.

The most famous of the older circus performers were the animal trainer L. Berousek-Berozini and the Knox tightrope walkers and jugglers. The star attractions of the 1960's and 1970's were the Vallo figure cyclists, the animal trainers J. Valašek, K. Malek, R. Crgak, and A. Šupka, the Bremlov jugglers, the clowns Bedalek, Vencin and Wiki, and I. Löfflör, the jumper Jeniček, and the aerialist M. Richterova.

Motion pictures

The first film showing took place in Prague in 1896, and documentaries and short acted films were made from 1898. Although the regular production of films had begun before World War I, the first permanent film studio was founded only after the establishment of the independent bourgeois Czechoslovak republic in 1918. The studio produced drawing-room melodramas, adventure and detective films, and comedies in the style of American films, mystical and fantasy dramas influenced by German expressionism, and pseudofolk comedies collectively known as the Kondelík Series (for example, *Father Kondelík and the Bridegroom Vejvara*, 1926).

Attempts to develop an indigenous cinematic art were discernible in the historical films *Czech Sky* (1918, directed by J. A. Palouš) and *Through Thorns to Glory* (1919, directed by R. F. Branald), in such screen adaptations of national literary classics as *The Good Soldier Švejk* (based on J. Hašek's novel, 1926, directed by K. Lamač) and *The Mountain Village* (after B. Němcová, 1928, directed by M. Krňanský), and in the exposé films *The Battalion* (1927, directed by P. Pražský), *Such Is Life* (1929, directed by K. Junghans), and *The Gallows-bird* (1930, directed by K. Anton). During the silent film era the leading film directors were Anton, M. Frič, S. Innemann, Krňanský, Lamač, G. Machatý, V. Kubásek, and J. Rovenský, and famous film stars included V. Burian, R. Deyl (senior), E. Fiala, F. Futurista, K. Hašler, A. Ondráková, J. Struna, and E. Štěpánek.

The first sound film, *When the Strings Are Weeping*, made by the German film director F. Feher, was released in 1930. Innovative techniques and an unusual treatment of the plot marked such films as *Before the Final Exam* (1932, directed by V. Vančura and Innemann), *The Inspector-General* (1933, a screen adaptation of Gogol's play directed by Frič, with V. Burian as Khlestakov and J. Marvan as the Mayor), and *Ecstasy* (1933, directed by Machatý). At the Second International Film Festival, held in Venice in 1934, the Czechoslovak films were awarded the Venice Prize for the best directing. The writers V. Nezval, K. Čapek, and I. Olbracht did much to strengthen the progressive trend in filmmaking. The year 1936 saw the release of the first joint Czech-Slovak film, *Jánošík* (directed by Frič), and of the lyrical film *The River* (directed by Rovenský). Among the talented new directors who emerged in the 1930's were V. Borský, M. Cikán, and O. Vávra. The first Slovak film, *Jánošík*, was made in 1921 by J. Siakel and F. Horlivý, who drew heavily on folk legends. K. Plicka made documentaries about Slovakia. One of Europe's largest film studios, releasing some 40 films annually before the war, was founded in 1933 at Barrandov near Prague.

During the fascist occupation German films were imported on a large scale. Nevertheless, Czechoslovak film-makers were able to produce several patriotic films: *Grandmother* (1940, based on Němcová's novella, directed by F. Čap), *Lawyer for the Poor* (1940, directed by V. Slavínský), and *Romance of May* (1942, directed by Vávra).

The Czechoslovak motion-picture industry was nationalized after the establishment of the people's democratic system in 1945. Besides re-creating heroic episodes from the country's history, as K. Steklý did in *The Siren*, based on M. Majerová's novel, film directors made motion pictures about the radical changes taking place in society and about the collectivization and class struggle in the countryside. These themes were explored in J. Krejčík's *Frona* (1954), Vávra's *The Offensive* (1952), and J. Mach's *Native Land* (1954).

In the late 1950's and early 1960's Czechoslovak cinematographers, eschewing stereotyping and a simplistic approach to the dialectically complex processes involved in the development of the new society and the new socialist personality, tried to portray the new life in all its diversity and complexity and to give meaning to the events of World War II. The finest of these films were J. Sequins' *Escape From the Shadows* (1958), V. Gajer's *Rabbits in the Tall Grass* (1962), A. Kachlík's *June Days* (1961), I. Novák's *Green Horizons* (1962), and Z. Brynych's *Transport From Paradise* (1962). Comedies ranged from satirical films tinged by the grotesque and fantasy to comedies of manners. Among the directors who excelled in this genre were O. Lipský, B. Zeman, V. Vorlíček, Z. Podskalský, and Mach. A number of outstanding cinematographers made their debut in the 1960's, notably Š. Uher, V. Chytilová, J. Jireš, and J. Menzel.

The complex ideological and political struggle that gripped the CSSR in the late 1960's also manifested itself in the production of a number of clearly antisocialist films. The efforts to strengthen the socialist positions in cinematography yielded positive results in the early 1970's. The finest traditions of socialist film art were developed in K. Kachyňa's *I'm Jumping the Puddles Again* (1970), V. Cech's *The Key* (1971), J. Jireš's *And Give My Love to the Swallows* (1972), J. Sequins' *Chronicle of a Hot Summer* (1973), and Vávra's *Days of Betrayal* (1974), *Sokolovo* (1974), and *The Liberation of Prague* (1976). Other excellent films of the 1970's were Lipský's *Three Men on the Road* (1973), Steklý's *Hippopotamus* (1974), J. Balík's *Lovers of the Year One* (1973), and Kachlík's *The Twenty-ninth* (1975). Many of these films deal with current social issues and the complex spiritual development of the contemporary hero.

The best Slovak films of the 1970's were M. Hollý's *The Copper Tower* (1970), J. Režucha's *Perfectly Honest Fellows* (1972), and Š. Uher's *A Great Night and a Great Day* (1975). The animators J. Trnka, K. Zeman, and H. Týrlova have made an international contribution to the development of the cartoon film.

The leading film stars are J. Marvan, F. Smolík, J. Bek, E. Kačírková, R. Hrušinský, J. Abrhám, V. Brodský, R. Růžek, M. Vášáryová, V. Fialová, F. Filipovský, V. Menšík, J. Króner, Š. Kvietik, and J. Sovak.

In 1976 there were six film studios in the country: Barrandov Film and Bratislava Koliba, both producing feature films, the Children's Film Studio in Gottwaldov, the Short Film Studio in Prague, the Newsreel Studio, and the Studio of the Czechoslovak People's Army. Sixty-eight feature films were released in 1976. Personnel are trained by the motion picture and television departments of the Prague Academy of Arts, founded in 1946. Research is conducted at the Czechoslovak Film Institute, which has a museum and a film library.

International film festivals were held in Mariánské Lázné from 1946 to 1949; in 1950 they were transferred to Karlovy Vary, where they have been held every two years since 1958. Children's film festivals were initiated in 1948.

The leading film magazines are *Film a doba* (Prague, since 1955), *Kino* (Prague, since 1946), and *Film a divadvo* (Bratislava, since 1959).

L. P. ERMILOVA [29–412–1]

CZECHOSLOVAK NEWS AGENCY (Československá Tisková Kancelář), the government-run information agency of the Czechoslovak Socialist Republic. Founded in Prague in Oct. 28, 1918, the agency is the chief source of domestic and international news for newspapers, radio, television, and government institutions. [29–504–3]

CZECHOSLOVAK PEOPLE'S PARTY (CPP; Československá Strana Lidová), a political party founded in February 1948 after the reorganization of a bourgeois party of the same name that had existed since 1918. The party essentially unites citizens holding a Christian world view, including farmers, craftsmen, workers, and members of the intelligentsia and some strata formerly belonging to the petite bourgeoisie. The party is active in the Czech Socialist Republic (CSR).

The party belongs to the National Front of the Czechoslovak Socialist Republic, recognizes the leading role of the Communist Party of Czechoslovakia, and supports the program of socialist construction in the country. It is represented in the Federal Assembly of the Czechoslovak Socialist Republic, the government of the Czech Socialist Republic, the Czech National Council, and the national committees (local governing bodies). The highest organ of the CPP is the Congress, which meets once every five years. Between congresses the party's activities are directed by the Central Committee (elected by the Congress), the Presidium, and the Secretariat of the Central Committee. R. Petera is the party chairman. The main press organ is the newspaper *Lidová demokracie* (People's Democracy). [29–501–2]

CZECHOSLOVAK RADIO (Československý Rozhlas), a government organization of the Czechoslovak Socialist Republic. Founded in 1923 in Prague, Czechoslovak Radio broadcasts in Czech and Slovak over five national networks (1980): Prague, Bratislava, Vltava, Děvín, and Hvězda. In some parts of Slovakia and in the northern Czech Socialist Republic programs are offered in Hungarian, Polish, and Ukrainian. Foreign broadcasts are made in Czech, Slovak, English, German, French, Russian, Italian, Spanish, Portuguese, and Arabic. In 1979 the organization operated 93 studios throughout the country. [29–504–1]

CZECHOSLOVAK SOCIAL DEMOCRATIC LABOR PARTY (CSDLP; Československá Sociálně Demokratická Strana Dělnická), a political party founded in April 1878 at a congress of Czech Social Democrats in Břevnov, near Prague, as a branch of the Austrian Social Democratic Party. It became an independent party in 1893. Until late 1918 the party was called the Czech-Slavic Social Democratic Labor Party.

In the late 19th and early 20th centuries the CSDLP headed the economic and political actions of the Czech proletariat. In 1910–11 the party split into the "autonomists" and the "centralists," the latter advocating a united trade union movement. During World War I the opportunist leaders of the autonomists took a social chauvinist stance. After the creation of a bourgeois Czechoslovak state in 1918, the party merged with the Slovak Social Democrats to form the CSDLP, led by the opportunists A. Němec and V. Tusar. (The centralists joined the CSDLP in March.) In December 1919 a revolutionary opposition crystallized within the CSDLP. Led by B. Smeral, J. Hybeš, and A. Zápotocký, the Marxist left, as the opposition was called, was to become the basis of the Communist Party of Czechoslovakia, founded in 1921. With the exception of a brief interval from 1926 to 1929, Social Democrats held cabinet posts in all the bourgeois coalition governments of Czechoslovakia from 1919 to 1938. After the Munich Pact (1938), the leaders of the CSDLP announced that the party had disbanded.

In 1945 the CSDLP was revived under the chairmanship of Z. Fierlinger, a member of its left wing. In November 1947 leadership was seized by the right wing, which elected as chairman B. Laušman and which collaborated in the preparations for the counterrevolutionary February events of 1948. In June 1948, the CSDLP purged its ranks of reactionary elements and merged with the Communist Party on a Marxist-Leninist basis.

K. P. GOGINA [29–501–3]

CZECHOSLOVAK SOCIALIST PARTY (CSP; Československá Strana Socialistická), a political party formed in February 1948 from part of the Czech National Socialist Party, which had been founded in 1897 and which had been called the Czechoslovak Socialist Party from 1918 to 1926. The CSP draws its support from several strata of the population that formerly belonged to the urban middle and petite bourgeoisie, as well as from a small portion of the intelligentsia, workers, and peasants. The party is active in the Czech Socialist Republic (CSR).

The CSP is a member of the National Front of the Czech Socialist Republic, recognizes the leading role of the Communist Party of Czechoslovakia, and supports the country's program of socialist construction. It is represented in the Federal Assembly of the Czechoslovak Socialist Republic, the government of the Czech Socialist Republic, the Czech National Council, and the national committees (local governing bodies). The party's highest organ is the national Conference, held once every five years. Between conferences, the party's activities are directed by the Central Committee, elected by the Conference. The chairman of the CSP is B. Kučera. The party's main press organ is the newspaper *Slobodné slovo* (Free Word). [29–502–1]

CZECHOSLOVAK TELEVISION (Československá Televize), a government organization of the Czechoslovak Socialist Republic. Founded in Prague in 1953, Czechoslovak Television broadcasts over two channels—Program I and Program II—from television studios in Prague, Bratislava, Brno, Ostrava, Košice, and a number of other cities. Color television was introduced in 1974. In 1979 the organization operated 34 repeater stations. [29–504–2]

CZECHOSLOVAK THEATER (full name, E. F. Burian Czechoslovak Theater), founded in Prague in 1933 by E. F. Burian as the D-34 Theater, the name being derived from the Czech word *divadlo*, meaning "theater," and the first year of the theater's operation.

The striving for modernity, underscored by the theater's name, was also reflected in its repertoire. Among its finest productions of the 1930's were Brecht's *Threepenny Opera* (1934), Hašek's *Good Soldier Švejk* (1935), Pogodin's *The Aristocrats* (1935), and Klicpera's *To Each According to His Deserts* (1936). The theater was subjected to police censorship and persecution for "propagating communism under the guise of art." In 1941 the theater was closed by the fascist authorities, and Burian was imprisoned in a concentration camp.

In 1945 the D-34 Theater reopened under the direction of Burian. Over the next four years it staged memorable productions of Káňa's *Grinder Karhan's Worker Team*, Čapek's *Mother*, Mayakovsky's *The Bedbug*, and Shtein's *Hotel Astoria*. After Burian's death in 1959, the D-34 Theater was renamed in his honor, and K. Novák served as its principal director until 1973. Outstanding productions of the 1970's included M. Bílek and V. Rón's *Play About Oton*, P. Neruda's *Splendor and Death of Joaquin Murieta*, Jirsíková's *May*, Vampilov's *Elder Son*, and Gorky's *Egor Bulychov and the Others*. In 1976, the theater's company included the directors E. Sokolovský and J. Palla and the performers J. Němeček, J. Valla, J. Holý, J. Langmiler, P. Olivá, V. Zinková, K. Burianová, and Z. Podlipná. The principal director (since 1973) is J. Větrovec, and the principal stage designer is V. Nývlt.

L. P. SOLNTSEVA [29–502–3]

CZECHOWICZ, JÓZEF. Born Mar. 15, 1903, in Lublin; died there Sept. 9, 1939. Polish poet.

A schoolteacher by profession, Czechowicz published the journal *Reflektor* in 1924 and 1925. His collections of verse include *Stone* (1927), *Ballad From the Other Side* (1932), and *The Human Voice* (1939). Czechowicz's verse re-creates the atmosphere of the Polish provinces and reflects a presentiment of the impending destruction of the bourgeois world. After beginning with formalist experimentation, he moved toward a realistic poetics. Czechowicz perished during Hitler's bombardment of Lublin.

CZECH PROGRESSIVE PARTY (Česká Strana Pokroková), a liberal bourgeois party that existed from 1900 to 1918. T. G. Masaryk was one of its founders and ideologues. Known as the Czech People's, or Realist, Party until 1905, the party drew its support from the Czech industrial bourgeoisie, which was loyal to the Austro-Hungarian monarchy and committed to bolstering its economic and political strength. The party advocated the autonomy of the Czech lands within Austria-Hungary, and in 1907 it sent two deputies to the Austrian Reichsrat. After the creation of a bourgeois Czechoslovak state in 1918, most of the party's members merged with the National Democratic Party, and the rest joined the National Socialist Party. [29–524–4]

CZECHS, a nation (*natsiia*, nation in the historical sense) in Czechoslovakia and the overwhelming majority of the population of the Czech Socialist Republic (CSR). Of the 9.6 million Czechs living in Czechoslovakia, 9.5 million reside in the CSR (1977 estimate). A considerable number of Czechs live abroad, chiefly in Austria, Canada, and the USA. The Czechs speak the Czech language. Most of the believers among them are Catholics, and the rest adhere to Protestant denominations.

In the fifth and sixth centuries, Slavic tribes settled and gained the ascendancy in the area now known as Czechoslovakia. Written sources have preserved the names of some of these tribes: Czechs, Doudlebi, Croats, Lučané, Zličane, Děčané, Pšované, Litoměřici, Hbané, and Glomači. The Czech tribe played a leading role in unifying these groups. In the ninth century, until 895, the Czech lands were part of the Great Moravian State. After its decline in the early tenth century, the center of political life shifted to Bohemia, where a state arose under the Czech Přemyslid dynasty. In the 11th century Moravia was merged with Bohemia. The Czech nationality that began to evolve in the Czech state at this time included the Moravians, who nevertheless preserved some of their ethnic distinctiveness. Beginning in the 13th century the ethnic homogeneity of the country was undermined by German colonization, which the Czech kings and feudal lords encouraged in order to increase their revenues. Growing German domination, increasing feudal exploitation of the Czech peasantry, and the corruption of the Catholic Church precipitated the Hussite revolutionary movement in the first half of the 15th century.

In 1620, after the battle of the White Mountain (Bílá Hora), the Czech lands lost their political independence and became a hereditary possession of the Hapsburgs. For three centuries the ruling circles of the Austrian Empire (after 1867, Austria-Hungary) pursued a policy of germanization in Bohemia and Moravia. By the 18th century, German had become the administrative language, and the popular masses were the sole transmitters of the Czech language and culture. In the late 18th and early 19th centuries, as the feudal system declined and capitalist relations arose, the modern Czech nation began to develop amid a growth of national consciousness. This period, known as the Czech Renaissance, saw the unfolding of a broad national movement and a campaign to revive the Czech language and to use it in all spheres of public life. Progressive writers and artists drew inspiration from the creativity of the people and introduced folklore themes in their works.

The collapse of Austria-Hungary in 1918 led to the creation of the first national state of Czechs and Slovaks, the Czechoslovak

Republic. In 1938–39 the republic was occupied by fascist German aggressors, who tried to suppress any manifestation of national life. The establishment of people's rule in 1945 and the subsequent socialist transformations in the country stimulated a general economic and cultural revival and permitted the formation of a socialist Czech nation.

Folk creativity has played a major role in the development of the Czechs' national culture—their literature, music, and art. In southwestern Bohemia (among the Chods) and in southeastern Moravia the national dress continues to be worn, and traditional crafts are flourishing. For more information about the history, economy, and culture of the Czechs, *see* CZECH SOCIALIST REPUBLIC and CZECHOSLOVAKIA.

CZECH SOCIALIST REPUBLIC (Česká Socialistická Republika, CSR), a republic in western Czechoslovakia (Czechoslovak Socialist Republic), encompassing the historical provinces of Bohemia and Moravia. With an area of 78,900 sq km and a population of 10 million (estimate, Jan. 1, 1976), the republic occupies more than 60 percent of Czechoslovakia's area and accounts for 68 percent of its population. Czechs constitute 94.2 percent and Slovaks 3.6 percent of the republic's population. Prague is the capital of both the republic and the country. The other major cities are Brno, Ostrava, Plzeň, Hradec Králové, Havířov, Olomouc, České Budějovice, Karviná, Pardubice, Liberec, Ústí, Gottwaldov, and Kladno. About two-thirds of the republic's population lives in urban-type settlements. Administratively, the CSR is divided into seven provinces: Central, South, West, North, and East Bohemia and South and North Moravia.

The Czech Socialist Republic is an equal and voluntary member of the Czechoslovak Socialist Republic, a federal state uniting the national states of the Czech and Slovak peoples. The CSR's system of government was established under the 1960 Constitution of the Czechoslovak Socialist Republic and the Constitutional Law of 1968 on the Czechoslovak Federation. The highest governing body is the Czech National Council, whose members are elected by the republic's population for five-year terms by universal, equal, and direct suffrage and secret ballot. The executive body, the government of the republic, is appointed by the Presidium of the Czech National Council.

Natural features. Most of the republic lies within the bounds of the Bohemian Massif, which is encircled by the medium-elevation ranges of the Šumava, the Bohemian Forest, the Ore Mountains, and the Krkonoše, rising to 1,602 m on Mount Sněžka. The interior of the Bohemian Massif, called the Bohemian Basin, consists of several lowlands separated by low-mountain massifs. Moravia, also a land of hills and low mountains, encompasses the Moravian Kras, with its karst formations, and the western spurs of the Carpathians. The Bohemian-Moravian Uplands occupy the southern and central parts of the republic. The climate is temperate, and the annual precipitation ranges from 450 mm to 600 mm in the plains and from 1,200 mm to 1,600 mm in the mountains. The mountain slopes are covered with mixed and coniferous forests.

Historical survey. The territory of the present-day republic was settled as early as the Lower Paleolithic. Celts arrived in the area circa 400 B.C., and from the second century B.C. the region was inhabited by the Celtic Boii tribes, from whom the Latin name Bohemia (German, Böhmen) is derived. At the beginning of the Common Era the Celts were overrun by the Marcomanni and other Germanic tribes. By the middle of the first millennium Slavic tribes had moved into the region, which was included in the state founded by Samo in the seventh century and formed part of the Great Moravian State in the ninth and early tenth centuries. Christianity, first Byzantine Orthodoxy and then Roman Catholicism, spread into Bohemia and Moravia in the ninth century.

Arising in the tenth century under the Přemyslid dynasty, the Prague Principality became the nucleus of an early-feudal Czech state. The princely authority and Czech state were considerably strengthened by Prince Břetislav I (ruled 1034–55). By this time the state ruled by the Přemyslids encompassed not only Bohemia (the historical region that today forms the western part of the Czech Socialist Republic) but also Moravia. In 1085 the Czech prince received the royal title, and in 1198 the Czech lands became a hereditary kingdom. In the period of feudal fragmentation, which lasted from the mid-11th to the late 12th centuries, the Czech lands were invaded by German feudal lords, who were defeated at Chlumec in 1126. The Czechs also routed the Mongol-Tatars who invaded Moravia in 1241.

A feudal estate monarchy arose in the Czech lands in the late 13th and the first half of the 14th centuries. After the Přemyslid dynasty died out in 1306, the Czech lands were incorporated into the domains of the Luxembourgs in 1310. Charles I, who was vicegerent of Bohemia and Moravia from 1333 and king of Bohemia from 1346 to 1378, was elected Holy Roman Emperor as Charles IV. Under Charles the importance of Prague increased, the Czech kings acquired the prerogatives of imperial electors in 1356, the Prague Archbishopric was established in 1344, and the University of Prague (Charles University) was founded in 1348.

Intensified feudal exploitation in the 14th and early 15th centuries strengthened the resistance of the Czech people to the oppression of the secular and spiritual feudal lords and the urban patricians, many of whom were Germans. (Colonization of the Czech lands by Germans had begun in the 13th century.) J. Hus played a leading role in the growth of the antifeudal and national liberation movement. In the first half of the 15th century the Czech lands were engulfed by a strong social-revolutionary, national liberation, and anti-Catholic movement (*see* HUSSITE REVOLUTIONARY MOVEMENT). The tyranny of the Czech magnates after the suppression of the Hussite revolutionary movement impelled the burghers of the Czech royal cities and the lower nobility to elect George of Poděbrady to the throne (ruled 1458–71). After his death the Czech magnates enthroned Vladislav II (ruled 1471–1516) and then Louis II (ruled 1516-26) of the Polish Jagiellonian dynasty.

After the Ottoman Turks defeated the combined Hungarian-Czech forces at the battle of Mohács in 1526, during which Louis II was killed, the Czech feudal lords elected the Austrian archduke Ferdinand I Hapsburg to the throne (ruled 1526–64). The Czech lands were to remain under the rule of the German-Austrian Hapsburgs until 1918. The rights and liberties of the Czech estates were restricted, and Germans became firmly entrenched in the bureaucracy, in the cities, and in commerce. The Reformation spread to the Czech lands in the 16th century. The Czech Uprising of 1547 was the first open rebellion against the Hapsburgs. The pro-German and Catholic policy of King Matthias (ruled 1611–19) fanned the discontent of the Czech estates, and the ensuing Czech uprising of 1618–20 signaled an international conflict that was to escalate into the Thirty Years' War (1618–48).

The defeat of the Czech estates at the decisive battle of the White Mountain (Bílá Hora) on Nov. 8, 1620, was followed by an "age of darkness" brought on by the triumph of feudal Catholic reaction in all spheres of the country's political, economic, and cultural life. Under the Revised Land Ordinance, promulgated in 1627, the Czech lands lost all vestiges of political independence. The growing feudal and national oppression provoked the Peasant uprising of 1680, the struggle of the Chods (*see* CHODS) in the late 17th century, and the Czech uprising of 1775, which obliged the Austrian government to reduce the *corvée* that same year. The personal dependence of the peasants was abolished in 1781.

The expansion of capitalist relations from the late 18th century was accompanied by the formation of a Czech bourgeois nation (*see* CZECHS). A national movement known as the Czech Renaissance unfolded in the Czech lands in the late 18th and the first half of the 19th centuries. Members of the Czech intelligentsia played a prominent role in fostering the people's national awareness and developing a national culture. Among these "awakeners" were J. Dobrovský, F. Pelcl, J. Jungmann, F. Palacký, and P. J. Šafařík. The Matice Česká, a cultural and educational society, was founded in 1831. In the Czech lands the Revolution of 1848–49 culminated in the Prague uprising of 1848. Although the

revolution was defeated, it resulted in the liberation of the peasants from feudal dependence and the abolition of the *corvée* in return for redemption payments.

The industrial revolution, which began in the Czech lands in the early 19th century, accelerated the development of capitalism. From the 1860's the Czech lands were transformed into the most industrialized part of the Hapsburg Empire, renamed Austria-Hungary in 1867. The liberal bourgeoisie that headed the Czech national movement split in 1874 into the conservative Old Czechs and the left-wing Young Czechs. From the late 1860's socialist ideas were disseminated by J. B. Pecka, L. Zápotocký, and J. Hybeš, and the growing strength of the workers' movement was manifested in the Svárov strike of 1870. The Czechoslovak Socialist Democratic Labor Party, founded in 1878, was part of the Social Democratic Party of Austria until 1893. At the end of the 19th century the strike movement assumed mass proportions; May Day of 1890 was marked by rallies and demonstrations. However, the Czech workers' movement was weakened by opportunism and the growing influence of bourgeois nationalism, whose mouthpiece was the Czech National Socialist Party, founded in 1897.

The Old and Young Czechs' support of the Austrian government gave rise to several new Czech political parties that reflected the interests of various groups of the Czech bourgeoisie: the Czech Radical Progressive Party (1897), the Czech Radical State Rights Party (1899), the Czech Agrarian Party (1899), and the Czech Progressive Party (1900). Under the influence of the Revolution of 1905–07 in Russia, large workers' demonstrations took place in the Czech lands, notably the general strike of Nov. 28, 1905. The Austrian government was obliged to consent to the introduction of universal suffrage in 1907.

After the outbreak of World War I a mass antiwar movement unfolded in the Czech lands. The Austrian government established a regime of police terror, suspended political freedoms, and set up military field tribunals. Most of the Czech bourgeois political parties adopted pro-Austrian positions, and the leadership of the Czechoslovak Social Democratic Labor Party pursued an opportunist policy. In 1915 pro-Entente bourgeois politicians headed by T. G. Masaryk founded the Paris-based Czechoslovak Foreign Committee, reorganized the following year as the Czechoslovak National Council. The February Revolution of 1917 and particularly the October Socialist Revolution in Russia gave impetus to the revolutionary movement in the Czech lands. The Czech working class took part in the general strike that spread across Austria-Hungary in January 1918 and in the May Day demonstrations of that year. In May 1918 the garrison of Rumburk in northern Bohemia rebelled in protest against the war. The October general political strike of 1918 in the Czech lands dealt a heavy blow to the Austro-Hungarian monarchy. On Oct. 28, 1918, amidst the collapse of Austria-Hungary, the National Committee in Prague (founded in 1916 and including representatives of all the Czech political parties from the middle of 1918) announced the formation of an independent Czechoslovak state. On Nov. 14, 1918, the Provisional National Assembly in Prague proclaimed the Czechoslovak Republic.

Down to the late 1930's the Czech lands, the most highly industrialized part of Czechoslovakia, were the main arena of class battles and antigovernment demonstrations. Such major confrontations as the December political strike of 1920 and the Most strike of 1932 were part of the struggle of the working class of all Czechoslovakia. The Communist Party of Czechoslovakia (CPC) was founded in 1921. The persecution of the CPC and other progressive organizations that began in the 1920's with the enactment of the Law on the Protection of the Republic (1923) intensified in the 1930's after several emergency laws were adopted in 1932–33. Under these conditions Czech fascist organizations, notably the National Union, stepped up their activity, and the fascist Sudeten German Party began campaigning in the northwest.

After the Munich Pact of 1938, by which the Sudeten region was ceded to Germany on October 1, the authorities disbanded the CPC and other progressive organizations in December. In March 1939, after the further dismemberment of the Czechoslovak state by fascist Germany, all the Czech lands except the areas detached in 1938 were declared the Protectorate of Bohemia and Moravia, to be administered by a Reich protector.

The aggressors established a fascist regime in the Czech lands, arresting about 6,000 Communists. After the outbreak of World War II the Nazis arrested more than 2,000 people, most of them members of the Czech intelligentsia, and incarcerated them in the German concentration camps of Dachau and Buchenwald. Communists headed the resistance movement in the Czech lands, which gained momentum after fascist Germany's attack on the USSR.

After an attempt on the life of the Reich protector R. Heydrich by Czechoslovak patriots on May 27, 1942, the Nazis intensified the mass repression. Some 1,800 people were executed. On June 10, 1942, the village of Lidice was wiped off the face of the earth, and on June 24 the same treatment was meted out to the village of Ležaky in Chrudim District. In the summer of 1942 partisan detachments organized by Czech patriots and by Soviet parachutists and prisoners of war who had escaped from German concentration camps began operating in the Brdy Forest, in the Beskids, and in other areas. The Slovak national uprising of 1944 spurred the resistance movement in the Czech lands. A clandestine Central Committee of the CPC was formed at the end of 1944 for the purpose of uniting all the resistance groups in Czechoslovakia and preparing for an armed uprising. Through the efforts of the CPC the Czech National Council, which included representatives of all the main groups in the resistance, was formed in the spring of 1945. The liberation movement in the Czech lands escalated under the influence of the successful offensive of the Soviet Army. Revolutionary national committees seized power in a number of cities and villages. During the People's Uprising of 1945, which broke out in the Czech lands in early May and which was supported by the Soviet offensive, Prague was liberated on May 9 as a result of the Prague Operation.

The liberation of the country from the fascist German aggressors created favorable conditions for the reunification of the Czech lands and Slovakia within a people's Czechoslovakia. The Košice Program, adopted on Apr. 5, 1945, proclaimed, among other democratic principles, the equality of the Czech and Slovak peoples. The restoration of Czechoslovakia's independence and the establishment of a people's democratic system heralded profound social and economic changes, including an agrarian reform, in both the Czech lands and Slovakia. In February 1948 the working people of the Czech lands, together with the working class and the laboring peasantry of the entire country, decisively defeated the bourgeoisie, which tried to stage a counterrevolutionary coup d'etat (*see* FEBRUARY EVENTS of 1948). The February victory opened the way for the building of a socialist society.

The Czech and Slovak peoples embarked on the building of socialism, whose victory in Czechoslovakia was legally reinforced by the Constitution of July 11, 1960. The CPC and the working people of the Czech lands helped implement measures aimed at eliminating the consequences of the actions of the antisocialist forces that tried in 1968 to detach Czechoslovakia from the socialist community (*see* CZECHOSLOVAKIA). The Constitutional Law, which was adopted by the National Assembly and went into effect on Jan. 1, 1969, transformed the Czechoslovak Socalist Republic into a federal state of two equal peoples, the Czechs and the Slovaks, and made the Czech Socialist Repubiic (CSR) one of two equal socialist republics in a federation.

G. E. SANCHUK (to the 18th century),
K. P. GOGINA (from the 18th century to 1918),
and O. P. SELIANINOV and A. KH. KLEVANSKII (since 1918)

Economy. The CSR has a highly developed industry and agriculture. In 1975 industry and construction employed 49.5 percent of the labor force, compared to 39.1 percent in 1948, and agriculture and forestry engaged 12.5 percent, as against 32.9 percent in 1948. The republic accounts for 74 percent of Czechoslovakia's national income, for 74 percent of its industrial output, for 66 percent of its construction, and for 67 percent of its agricultural output.

In the course of socialist construction, the national income increased by a factor of about 5 between 1948 and 1975, the industrial output by a factor of 7.7, and the agricultural output by a factor of 1.8. The economy of the republic has been radically reorganized and modernized. The structure of industry has been altered by the rapid expansion of the machine-building, metal-

working, and chemical industries, whose output rose by a factor of more than 17 from 1948 to 1975. The main branches of the republic's highly diversified industry are fuel and energy (accounting for 10 percent of the total gross output of the CSR), ferrous metallurgy (10.6 percent), machine building and metalworking (32.8 percent), chemicals (6.8 percent), textiles (6.1 percent), and food and condiments (14.8 percent).

The CSR produces all the bituminous coal mined in Czechoslovakia; most of the 28 million tons extracted in 1975 came from the Ostrava-Karviná and Kladno basins. The republic also accounts for most of the country's brown coal output (more than 80 million tons in 1975), extracted from the North Bohemian and Sokolov basins, and for the greater part of the electric power generated (about 50 billion kW-hrs in 1975). A large metallurgical and machine-building complex has been established. In 1975 most of the republic's output of 9 million tons of coke, more than 6 million tons of cast iron, more than 10 million tons of steel, more than 7 million tons of rolled metals, and more than 1.2 million tons of pipes came from three metallurgical plants in the Ostrava-Karviná Basin. The CSR accounts for three-fourths of the country's machine-building output and for almost its entire output of power equipment, means of transportation, machine tools, tractors, electrical engineering goods, and certain other types of machinery and equipment.

The large chemical industry manufactures, in addition to inorganic chemical products derived from coal, organic chemical products obtained by processing hydrocarbon raw materials, chiefly petroleum. Major products include plastics, chemical fibers, and synthetic rubber. Most of the chemical enterprises are situated in the North Bohemian Brown Coal Basin, along the middle and lower Labe, and around Ostrava. Cement and other building materials are produced on a large scale. North Bohemia has numerous glassworks, and West Bohemia is famous for its porcelain. The logging and woodworking industry of the mountain regions produces paper, furniture, and pencils. The textile industry, a traditional industry in North Bohemia, manufactures cotton, wool, silk, and linen fabrics and clothing. The leather and footwear industry, concentrated in Gottwaldov, produces for the world market. The main products of the thriving food and condiments industry are refined sugar and beer. The most important industrial regions are the Prague-Plzeň region, Brno and its environs, the Ostrava-Karviná region, the area along the Labe River, and central Moravia.

The republic's agriculture is highly intensive, market-oriented, and diversified. In addition to grain crops, beets, potatoes, fodder crops, hops, fruit, and vegetables are widely grown. Wheat, sugar beets, and barley are cultivated mainly in the fertile valleys of Moravia and along the Labe; rye and potatoes are grown in the hilly areas. Animal husbandry is flourishing; beef and dairy cattle, hogs (mechanized farms), and poultry are raised. Commercial pond fishing is important. The CSR is situated at the junction of important European transportation routes. The Vltava and the Labe are used for shipping. L. A. AVDEICHEV

Cultural affairs and public health. In the 1975–76 school year about 317,000 children attended 6,203 kindergartens admitting children between the ages of three and five years. That year about 1.2 million pupils were enrolled in 5,908 compulsory primary schools, about 72,000 students in four-year secondary general-education schools (*Gymnasiums*), about 215,000 students in vocational schools, and more than 183,300 students in three- or four-year secondary vocational schools. The republic's 23 higher educational institutions had an enrollment of about 92,300. The largest and oldest institutions of higher learning in Prague are Charles University (University of Prague), founded in 1348 and attended by more than 24,100 students in the 1976–77 academic year, the Technical University, higher schools of chemical technology, economics, and agriculture, the Academy of Art, and the Academy of Fine Arts. Located in Brno are the University of Brno, the Technical University, and the L. Janáček Academy of Music and Dramatic Art. Two other major schools are the F. Palacký University in Olomouc and the State College of Mining and Metallurgy in Ostrava.

The highest scientific institution is the Czechoslovak Academy of Sciences, some 70 of whose research institutes and other scientific institutions are located in the republic, chiefly in Prague and Brno. In addition, various scientific sections of the Czechoslovak Academy of Agriculture, which was detached from the Academy of Sciences in 1974, are based in the republic. Prague is the site of several research institutes affiliated with ministries and agencies of the Czechoslovak government, notably the Geological Survey (founded 1919), the Hydrometeorological Institute (1920), and the Water Research Institute (1920). Outside Prague, there are major specialized research institutions in Brno, Ostrava, Gottwaldov, Olomouc, and Jihlava. Scientific work is also conducted at higher educational institutions, some of which maintain research institutes. Attached to the University of Prague, for example, are institutes of Marxism-Leninism (1970) and astronomy (1887), and the School of Economics in Prague has established an institute of industrial economics. There are a number of learned societies.

The largest libraries in Prague are the State Library of the Czech Socialist Republic (founded 1958; 4.6 million volumes in 1976), the Library of the Czechoslovak Academy of Sciences (1952; more than 700,000 volumes), the National Museum Library (1818; 2.4 million volumes), the City Library (1891; 2,048,000 volumes), and the State Technical Library (1707; 724,000 volumes). Brno's largest libraries are the State Technical Library (1899; 1.1 million volumes) and the University Library (1815; 1,689,000 volumes). Research libraries have also been established in Opava, Ostrava, Olomouc, Plzeň, and other cities.

The principal museums are the National Museum, founded in Prague in 1818, the National Gallery (1796) in Prague, the Museum of the Capital City of Prague (1883), the Brno Municipal Museum (1904), and the Moravian Museum (1818) in Brno. Also important are the city museums in Karlovy Vary and Pardubice and the regional museums in Gottwaldov, Teplice, and Opava.

In 1975 the republic had 18 daily newspapers, 186 weeklies, 112 biweekly magazines and newspapers, and 282 monthly magazines; 4,310 books and pamphlets were published, totaling more than 58,000 copies. The most influential dailies, all published in Prague, are *Rudé právo* (since 1920; 1975 circulation, about 1 million), the organ of the Central Committee of the Communist Party of Czechoslovakia; *Práce* (since 1945; circulation, about 290,000), the organ of the Czechoslovak Revolutionary Trade Union Movement; *Mladá fronta* (since 1945; circulation, 238,000), the organ of the Socialist Union of Youth; *Svobodné slovo* (since 1945; circulation, 227,800), the organ of the Czechoslovak Socialist Party; and *Lidová demokracie* (since 1945; circulation, 216,900), the organ of the Czechoslovak People's Party.

Czechoslovak Radio, founded in 1923, and Czechoslovak Television, inaugurated in 1953, are government organizations of the Czechoslovak Socialist Republic. Most of the radio broadcasting is done by the Prague Radio Station, which broadcasts five programs. Television studios in Prague, Brno, Ostrava, and Plzeň broadcast two programs each.

In 1975 the republic had 5,762 hospitals and maternity homes, 615 specialized medical facilities, 433 therapeutic sanatoriums, 509 medical research institutes, and 76 clinics for safeguarding the health of mothers and infants. That year there were 27,896 doctors, or one for every 362 inhabitants.

Health resorts such as the world-famous spas of Karlovy Vary, Mariánské Lázně, Františkovy Lázně, and Poděbrady have developed around the republic's many mineral springs.

Literature. The appearance of the earliest Czech literary works—religious songs, saints' lives, and legends written in Old Church Slavonic—was made possible by the educational activity of the brothers Cyril and Methodius and their disciples at the turn of the tenth century. In the late 11th century, as the Roman Church became stronger, Old Church Slavonic was displaced by Latin. The most important medieval work in Latin was the *Czech Chronicle* (1125) by Cosmas of Prague. A vernacular and secular literature emerged in the late 13th century. The spread of Renaissance ideas into Bohemia and Moravia promoted the flowering of Czech literature in the 14th century. A remarkable historical work was the Boleslav (or Dalimil) Chronicle, composed in verse between 1308 and 1314 by Dalimil Mezířičský. Fourteenth-century Czech literature included satirical and didactic works, such as the folk drama *The Seller of Medicinal Ointments*, chivalric tales and epics, love lyrics, and the lyric and satirical songs of the *vagants*, wandering monks and students. The first known Czech

writer was the satirist S. Flaška (mid-14th century to 1403), whose works reflect a conflict between the king and the feudal nobility. The works of T. Štítné (circa 1333–1405) inveighed against foreign domination and foreshadowed the coming struggle for religious reform.

A new phase in literary development opened with the Hussite revolutionary movement of the first half of the 15th century, which produced anti-Catholic sermons (Jan Hus [c. 1371–1415] and Jan Želivský [died 1422]), epistolary works (Jan Hus and Jan Žižka [c. 1360–1424]), leaflets, manifestoes, appeals in verse (*Prague's Dispute With Kutná Hora*), and battle songs ("Those Who Are God's Warriors"). After the suppression of the Hussite movement, its patriotic spirit was kept alive by such writers as P. Chelčický (c. 1390–1460).

In the Czech lands the first printed books were issued in 1468. With the consolidation of feudalism in the late 15th century, Czech authors turned to scholarly writing. Some works protested against ossified medieval traditions. Chronicle writing flourished in the 16th century.

The domination of Catholicism in the 17th and 18th centuries hindered literary development. Latin was once again given preference over Czech, books written in Czech were destroyed, and many writers emigrated. An unwavering humanitarianism distinguished the pedagogical writings and philosophical literary works of the leading writer of that time, J. A. Comenius (1592–1670), one of whose best-known works was *The Labyrinth of the World and Paradise of the Heart* (1623). Apart from the official literature, serving the aims of Catholic propaganda, Czech books circulated in manuscript form, copied by anonymous scribes who wished to preserve them for future generations. Love lyrics were composed in the baroque style. Oral folk poetry played an important role in the spiritual life of the Czech people during these centuries.

L. S. KISHKIN

The literature of the Czech national renaissance, spanning the late 18th and first half of the 19th centuries, was in large measure shaped by the "awakeners." It initially arose as an Enlightenment literature championing the ideals of rationalism (J. Dobrovský, 1753–1829) and the use of the Czech language, in which odes, fables, and secular lyrics were written (A. J. Puchmajer, 1769–1820). In the second and third decades of the 19th century the philologist and poet J. Jungmann (1773–1847) and the publicist P. J. Šafařík (1795–1861) formulated a program for the development of an indigenous national literature. Essentially preromantic, the works produced between 1810 and 1830 drew on folklore, poeticized the heroic past, and affirmed the kinship of the Slavic peoples and their cultures. Two major early 19th-century works, known as the Králové Dvůr (1817) and Zelená Hora (1818) manuscripts, were written by V. Hanka (1791–1861) and J. Linda (1789–1834) in the style of ancient patriotic legends and passed off as genuine historical texts. Other important works included the narrative poem *Daughter of Sláva* (1824, 2nd ed. 1832) by J. Kollár (1793–1852), the bard of Slavic brotherhood, and the verse collections *Echo of Russian Songs* (1829) and *Echo of Czech Songs* (1839) by F. L. Čelakovský (1799–1852). The revolutionary romanticism of the 1830's brought to literature, along with a passionate longing for freedom and subjective lyricism, a broad range of philosophical issues. Its leading exponent was K. H. Mácha (1810–36), best known for his lyrical narrative poem *May* (1836). Dramaturgy was represented by J. K. Tyl (1808–56).

During the Revolution of 1848–49 realist tendencies emerged in Czech literature, whose social criticism and heroic and patriotic overtones became stronger, as illustrated by Tyl's plays *The Miners of Kutná Hora* (1848) and *Jan Hus* (1849). Antiabsolutist and anticlerical satire appeared in the narrative poems of K. Havlíček-Borovský (1821–56), the author of *Tyrolean Elegies* (1852, published 1861) and *The Baptism of St. Vladimir* (1848–54, complete text published 1876). During the Hapsburg reaction of the mid-19th century the novellas of B. Němcová (1820–62) mirrored social antagonisms and portrayed the common people as the main bearer of moral and ethical values (*The Grandmother*, 1855). K. J. Erben (1811–70) carried on the romantic folklore traditions in his *Bouquet* (1853), a collection of ballads.

From the 1860's to the 1880's realism developed further, its principles expounded in the critical articles of J. Neruda (1834–91). Realist poetics are affirmed in the civic verse and intimate lyrics of Neruda's *Book of Poems* (1868), *Simple Motifs* (1883), and *Ballads and Romances* (1883). Neruda also introduced urban themes into literature, frequently ridiculing the petite bourgeoisie, as in the *Tales of the Little Quarter* (1878). Social and moral issues were raised in two fine novellas about rural life: *In the New Village* (1873) by V. Hálek (1835–74) and *A Village Romance* (1869) by K. Světlá (1830–99).

By the early 1890's social criticism became more pronounced in realism, and writers evinced a heightened interest in the individual's relationship to society and man's inner world. Several outstanding historical novels were written. A. Jirásek (1851–1930) re-created critical moments of Czech history, portraying the panorama of the Hussite movement as a people's liberation war in *Between the Currents* (vols. 1–3, 1887–90) and *Against Everyone* (1893). The social conflicts of their own day were depicted by A. Stašek (1843–1931) in the novel *In the Turbid Whirlpool* (1900) and by J. Arbes (1840–1914) in the novel *Modern Vampires* (1882).

Criticism of social evils, patriotism, and a romantic anticipation of revolutionary changes infused the narrative poem *Songs of a Slave* (1894) by S. Čech (1846–1908), the collection *Village Songs and Bohemian Sonnets* (1890) by J. V. Sládek (1845–1912), and the collection *Fragments of an Epic* (1886) by J. Vrchlický (1853–1912). The realist plays *Her Stepdaughter* (1890) by G. Preissová (1862–1946), *Maryša* (staged 1894) by A. Mrstík (1861–1925) and V. Mrštík (1863–1912), and Jirásek's *Woman Warrior* (1890) and *The Father* (published 1895) depicted the tragic fate of the peasants and showed the impact of capitalist relations on the countryside.

At the turn of the century the literary scene was marked by diversity and contradiction. Although literature was clearly influenced by the labor movement and socialist ideas, the rejection of bourgeois reality was often accompanied by individualistic rebellion, which prompted the *Manifesto of the Czech Modernists* (1895). While condemning bourgeois relations, the poetry of J. S. Machar (1864–1942), notably his collections *Tristium vindobona* (1893) and *Golgotha* (1901) and his narrative poem *Magdalena* (1894), offered no clear alternatives. A spirit of spontaneous proletarian class protest animated the *Silesian Songs* (published separately in 1909) of P. Bezruč (1867–1958).

Modernist and decadent trends, finding extreme expression in the magazine *Moderní revue* (1894–1925), had only a partial influence on such writers as V. Dyk (1877–1931), whose principal poetic works were imbued with antimilitarist and patriotic fervor. Dreams of a humane world and freedom were typical of the symbolist poets, notably O. Březina (1868–1929), best known for his collection *Hands* (1901), and A. Sova (1864–1928), author of the collection *The Adventure of Daring* (1906). K. M. Čapek-Chod (1860–1927) portrayed society's ills in a naturalist vein. Anarchist feelings pervaded literature. A spirit of rebellion marked the early symbolist-influenced poetry of S. K. Neumann (1875–1947), gathered in the collections *The Glory of Satan Among Us* (1897) and *A Dream About a Crowd of Desperate People and Other Verses* (1903). The same defiant spirit informed the poetry of K. Toman (1877–1946), F. Šrámek (1877–1952), and F. Gellner (1881–1914). The short stories, pamphlets, and feuilletons of the brilliant Czech satirist J. Hašek (1883–1923) expressed the hatred of the lower classes for the Hapsburg monarchy, the social elite, the bourgeois bureaucratic system, and militarism. I. Olbracht (1882–1952) and M. Majerová (1882–1967) began their careers in the early 20th century.

S. V. NIKOL'SKII

The establishment of the Czechoslovak Republic in 1918 and the upsurge in the country's labor movement opened up new prospects for the development of literature. The Great October Socialist Revolution had a strong influence on the evolution of progressive Czech literature. A revolutionary trend emerged in the 1920's; its leading exponents were Z. Nejedlý (1878–1962), Neumann, Olbracht, Majerová, and young writers and artists of the Devětsil group. The theoreticians of proletarian poetry, which appeared in the early 1920's, were Neumann, J. Hora (1891–1945), and J. Wolker (1900–24). Revolutionary motifs were developed in the collection *A City in Tears* (1921) by

J. Seifert (born 1901), and Neumann's collection *Red Songs* (1923) introduced new kinds of civic and agitation lyrics. Wolker's works, notably his collection *Hour of Birth* (1922), embodied the ideals of revolutionary humanism; his poetics reflected a love of metaphor and experimentation with new forms of free verse. V. Nezval (1900–58) took a highly original approach to revolutionary romanticism in his narrative poem *The Amazing Magician*.

In the mid-1920's Devětsil rejected the program of proletarian poetry and advanced an avant-garde theory of poetics claiming that true revolutionary art was "pure lyricism." This notion was expounded by the theoretician K. Teige (1900–51) and the poets Nezval, Seifert, and K. Biebl (1898–1951). Despite such pronouncements, however, the best works of the Devětsil poets remained in the proletarian tradition. Nezval's narrative poem *Edison* (1928) was an innovative masterpiece of revolutionary art. Among the best proletarian prose works of the 1920's were Hašek's antimilitarist and satirical novel *The Good Soldier Švejk* (1921–23, unfinished), Majerová's realist novel *The Best of Worlds* (1923), Olbracht's realist novel *Anna the Proletarian* (1928), and the novel-parable *The Baker Jan Marhoul* (1924) by V. Vančura (1891–1942). Critical realism was continued by A. M. Tilschová (1873–1957), K. Nový (born 1890), and B. Klička (1897–1943). K. Čapek's novels and plays were an unusual blend of antibourgeois satire and social utopianism.

In the 1930's the Marxist critics J. Fučík (1903–43), B. Václavek (1897–1943), K. Konrad (1908–41), and L. Štoll (born 1902) worked on the theoretical problems of socialist realism. Writers of the Left Front, founded in 1930, polemicized with the group of surrealists formed by Nezval in 1934. The advocates of socialist realism formed the Alliance in 1935, which also included Slovak writers. The progressive camp opposed the Catholic writers, notably J. Durych (1886–1962), and the ruralism that reflected the ideology of the reactionary Agrarian Party. A prominent place was held by the civic and philosophical lyrics of Neumann and the proletarian poetry of J. Noha (1908–66), J. Taufer (born 1911), and F. Nechvátal (born 1905). Besides surrealist poems, Nezval wrote political poems on current themes. The poetry of V. Závada (born 1905) dealt with social concerns, and Neumann and F. Halas (1901–49) wrote poems about the Spanish Civil War. A very different voice was heard in the existential poetry of Halas and V. Holan (born 1905) and in the "pure lyricism" of Hora and Seifert. In the face of Nazi aggression, the progressive Czech poets were united in their dedication to antifascist and patriotic literature.

The socialist realist novel flowered in the 1930's. Social consciousness was combined with profound psychological analysis in the novels *The Siren* (1935) by Majerová, *People at the Crossroads* (1937, first part of a trilogy) by M. Pujmanová (1893–1958), *The Shoe Machine* (1933) by T. Svatopluk (1900–72), *The Sources* (1924–33; unfinished) by J. Kratochvíl (1885–1945), and *Three Rivers* (1936) by Vančura. In Olbracht's novel *Nikolaj Šuhaj, Bandit* (1933) motifs from folk legends are skillfully woven into the realist fabric of the work. Fučík and Pujmanová produced essays, reportage, and books about the USSR. Čapek's satirical and philosophical antifascist novel *War With the Newts* (1936) gained world renown. It was followed by two fine antifascist plays, *The White Plague* (1937) and *Mother* (1938). Vančura abandoned abstract philosophical dramaturgy in favor of realist plays.

Avant-garde literary criticism was represented in those years by Teijge and "academic" criticism by the Prague structuralists (*see* PRAGUE, LINGUISTIC CIRCLE OF). F. Šalda analyzed literature from a general democratic perspective.

During World War II, Vančura, Fučík, Konrad, Kratochvíl, Václavek, and other writers died in fascist prisons and concentration camps. Literature was full of the ideas of the antifascist resistance, eloquently expressed in Vančura's *Scenes From the History of the Czech People* (vols. 1–3, 1939–40), Fučík's *Notes From the Gallows* (published 1945), and the poetry of Halas and Neumann.

In the first postwar years, the people's liberation struggle and the victory over fascism was a central theme in Czech literature, notably in the poetry of F. Hrubín (1910–71), Nezval, Holan, Halas, and Pujmanová and the prose of J. Drda (1915–70). Nevertheless, representatives of bourgeois ideology remained influential. The victory over reaction in February 1948 marked the beginning of a new stage in the struggle for socialist literature.

In the 1950's prose writers showed a predilection for epic panorama. The historical destiny of the Czech people and their path to socialism were depicted in novels by Pujmanová (*Playing With Fire*, 1948; *Life Against Death*, 1952) and A. Zápotocký (1884–1957). Socialist construction was the theme of the novels *The Offensive* (1951) and *The Battle* (1954) by V. Řezáč (1901–56), *Without a Chief* (1953) by Svatopluk, and *The Peasant* (vols. 1–2, 1955–58) by B. Říha (born 1907). The complex conflicts of modern times were explored by J. Otčenášek (born 1904) in the novel *Citizen Brych* (1955) and by Z. Pluhař (born 1913). The antifascist struggle, a persistent theme, was portrayed in *Lame Orpheus* (1964) by Otčenášek and *Box for the Living* (1956) by N. Frýd (1913–76). V. Neff (born 1909) and J. Toman (1899–1977) wrote historical novels. The narrative poem *Song of Peace* (1950) and other works by Nezval became known throughout the world. The poetry of Závada, Hrubín, Taufer, and I. Skála (born 1922), imbued with antiwar fervor, evoked the spiritual world of modern man. Other poets, notably M. Florian (born 1931), chose to write about intimate personal experiences and the beauty of the Czech landscape. Hrubín also wrote psychological plays about contemporary life (*Crystal Night*, 1961), and Nezval created the antiwar philosophical fantasy play *Today the Sun Still Sets Over Atlantis* (1956).

Nihilist tendencies emerged in the mid-1960's, becoming strong during the political crisis of 1968, when they often turned into a rejection of socialism. The influence of Western modernism—the "new novel," the theater of the absurd, and "concrete" poetry—became increasingly apparent. After the April Plenum of the Central Committee of the CPC (1969), a campaign was launched to overcome the consequences of the crisis in ideology, culture, and literature. The Union of Czech Writers, founded in May 1972, united the Czech literary forces around socialist realism.

In the early 1970's continuity was restored with the best traditions of the preceding period, and socialist literature experienced a strong revival. Significant poetic works have been created by Závada, whose collection *On the Threshold* (1970) was widely acclaimed, Taufer, Skála, J. Rybák (born 1904), Florian, and V. Hons (born 1938), best known for his narrative poem *February* (1973). The problems of building a new society and developing a socialist morality are posed in the novels *St. Michael* (1971) and *The Stork's Nest* (1976) by J. Kozák (born 1921), *Doctor Meluzín* (1973) by Říha and *My Boy and I* (1974) by J. Kolárová (born 1919). Influential literary critics have included Štoll, Taufer, J. Hájek (born 1919), V. Dostál (1930–75), Š. Vlašín (born 1924), H. Hrzalová (born 1929), and V. Rzounek (born 1921).

S. A. SHERLAIMOVA

Architecture and art. Archaeological excavations in Bohemia and Moravia have yielded Paleolithic figurines, Neolithic pottery (grooved ware, *Bandkeramik*, and corded ware), and art works of the Proto-Slavs and of the Hallstatt and La Tène cultures. Ancient Slavic pottery of the Prague type has survived from the seventh century. Silver, gold, and bronze jewelry has been found among the remains of fortified Slavic settlements dating from the eighth to the tenth centuries. The most important such sites are in Prague and Staré Město near Uherské Hradište.

After the adoption of Catholicism, stone churches were built, some conforming to Byzantine models (ruins of a ninth-century church near Staré Město) and others to Western European, mainly Carolingian, prototypes (St. Vitus Rotunda in Prague, c. 930). The Romanesque style, which flourished from the 11th to the 13th century, determined the austere forms of the 11th-century St. Vitus Basilica and the 12th-century St. George Basilica in Pražský Hrad. Stone houses and fortifications were built in the cities that arose around the castles of feudal lords. A fusion of German and Byzantine influences is discernible in the art of the 11th to 13th centuries, notably the Vyšehrad Codex miniatures (1085) and the wall paintings depicting members of the Přemyslid dynasty in the St. Catherine Rotunda in Znojmo (1134). The reliefs decorating the 12th-century St. George Basilica in Pražský Hrad are notable for their highly expressive simplified forms.

From the mid-13th to the mid-15th century the consolidation of the feudal state, the rise of an urban culture, and the turbulent social movements that erupted into the Hussite wars contributed to a flowering of Gothic architecture and art. Severely majestic forms and restrained magnificent decoration, clear in design, are characteristic of 14th-century Gothic buildings. The finest examples of the Gothic style in Bohemia may be found in Prague: the eastern section of the St. Vitus Cathedral with its graceful reticulated vaults (the building of the cathedral, begun in 1344, was continued by Peter Parler from 1356 to 1399), the 14th-century Town Hall of the Old Town, and the 14th-century buildings of Charles University. The bridges built in the 13th and 14th centuries in Prague (Charles Bridge, 1357–78, P. Parler), Pisek, and Roudnice are noteworthy for their bold arch design. In the 14th and 15th centuries reconstructed older cities and new urban centers (New Town in Prague) acquired a regular layout and a rectangular central square (České Budějovice, Telč, Český Krumlov). The castles built by feudal lords between the 13th and 16th centuries consisted of a fortified center and a surrounding settlement; the castle proper usually had a donjon, a chapel, inner courtyards with Gothic arcaded galleries, and grand halls with reticulated vaults, as illustrated by the castles in Křivoklát (13th–16th centuries) and Zvíkov (13th century). Blending naturally with the landscape, Karlstein Castle is remarkably harmonious in composition.

In the second half of the 15th and the early 16th centuries the decorative element grew stronger in architecture, and vault patterns became more elaborate, as may be seen in Vladislav Hall in Pražský Hrad (architect B. Rejt) and the Cathedral of St. Barbara in Kutná Hora. Basilican churches were replaced by hall churches, the finest example of which is the Church of the Ascension of St. Mary in Most, built in the first half of the 16th century. Even some town halls, notably that of Tábor (14th–16th centuries), were built as halls divided by aisles.

The fine art of the 14th century creatively assimilated the artistic traditions of France, Germany, and Italy. In sculpture canonically strict images (*Madonna of Strakonice*, mid-14th century) yielded to a penchant for lyricism and elegant representation (statues of the Master of the *Michelska Madonna*, second quarter of the 14th century). In painting, some artists combined delicate drawing with an attempt at modeling (*Roudnice Predella*, c. 1340), while others strove for realistic composition and vibrant coloration (Master of the Vyšší Brod Altar, mid-14th century).

The realist tendencies in Gothic art reached their peak in the second half of the 14th century in the reign of Charles IV. The busts carved in the triforium of the St. Vitus Cathedral in Prague (1374–85, P. Parler) are noteworthy for their striking individual traits and clarity of plastic form. The panels depicting saints in the chapel of Karlstein Castle (c. 1357–67, Master Theodoric) are distinguished by a monumental quality, keen observation, and soft modeling. In the more dramatic paintings of the Master of the Třeboň Altar (fourth quarter of the 14th century) the images are highly individualized, and the color scheme gains an emotional intensity. The "soft style" became popular in the late 14th century. In the early 15th century art became more secular and at times even anticlerical, as evidenced by the early 16th-century miniatures of the Jena Codex. The finest example of Bohemian manuscript illumination of the 14th and 15th centuries is the *Passional of the Abbess Kunhuta*, completed before 1320. Bohemian craftsmen excelled in artistic glasswork, silver and gold embroidery, and the making of jewelry, stained glass, and mosaics.

After the establishment of Hapsburg rule in 1526, the Renaissance style was introduced into Bohemia, chiefly by Italian architects. The most famous Renaissance structures, all in Prague, are the Belvedere Palace, surrounded by an elegant arcaded gallery (c. 1535–63), the games court in the royal garden (1560's), and the Schwarzenberg Palace. Castles rebuilt in the Renaissance style acquired galleries with columned arcades, loggias, and grand halls (Pardubice, Jindřichův Hradec). In the second half of the 16th and early 17th centuries a highly original Renaissance style evolved in urban construction through the mingling of Renaissance and still vigorous Gothic forms. The homes of wealthy burghers were decorated with ornate pediments and attics, arcaded galleries, balconies, and sgraffito murals (Tábor, Telč, Pardubice, and Litoměřice).

In the late 15th and the 16th centuries Renaissance influences affected altar painting, which reached a high level in the work of the Master of the Litoměřice Altar. Secular genres developed, such as stucco decoration, sgraffito wall painting, and simplified tombstone sculpture portraying the dead. At the turn of the 17th century Prague was one of the last centers of European mannerism, which was cultivated by Italian, Dutch, and German masters, notably B. Spranger, G. Arcimboldo, and A. de Vries, who worked at the court of Rudolph II.

A new architectural revival began in the second half of the 17th century, when the baroque style became popular in palace architecture. The baroque buildings erected in Prague, all original interpretations of Italian, Austrian, and French architecture, are marked by flexible composition, festive grandeur, and elegant decoration. The most impressive of them are the Černín Palace (1669–1750), the Kinský Palace (begun 1755, architect K. I. Dientzenhofer), and the Clam-Gallas Palace (c. 1713, architect J. B. Fischer von Erlach). The palaces were surrounded by elaborate garden and park complexes. The Gothic silhouette of the cities was modified by baroque churches, either single-aisled or circular structures with majestic domes, multitier towers, and lavish sculptural decoration. An outstanding example is the Church of St. Nicholas in Malá Strana, Prague (1704–55), designed by the architect K. I. Dientzenhofer.

Bohemian baroque art of the 17th and 18th centuries evinced realist and democratic tendencies, which are especially strong in the portraits and murals of K. Škréta and P. Brandl, the splendid, eloquent frescoes and landscapes of V. V. Reiner, the portraits of J. Kupecký, the engravings of V. Hollar, and the still lifes of R. Byss and J. V. Angermayer. The leading sculptors were M. B. Braun and F. M. Brokoff, who together produced many of the expressively modeled statues on the Charles Bridge in Prague in the late 17th and early 18th centuries. Rococo and classical influences appeared in the mid-18th century in the sculpture of I. Platzer and the fine genre paintings of N. Grund. Artistic glasswork, metalwork, and embroidery reached a high level of excellence in the 17th and 18th centuries.

In the late 18th and early 19th centuries, the period known as the Czech Renaissance, when the national liberation movement spread through the Czech lands, art joined the struggle for national self-assertion. After a brief and limited triumph of classicism, a national romantic style, marked by eclecticism, became firmly established in architecture after 1850. The grand monumentality and rich ornamentation of the neo-Renaissance and neo-baroque edifices built between the 1860's and the 1890's may be seen in the National Theater (1868–83, architects J. Zítek and J. Schulz), the Rudolfinum (1876–84), and the National Museum (1885–90), all in Prague. In the late 19th and early 20th centuries the *art nouveau* style yielded to nationalist trends, reflected in the buildings designed by J. Kotěra in Hradec Králové and Prostějov and by O. Novotný in Prague.

The development of art was promoted by the founding in Prague of the Patriotic Society of the Friends of Art (1796) and the Academy of Arts (1799). In the first half of the 19th century, realistic tendencies emerged alongside the prevailing classicism and romanticism. Themes from national history and representations of contemporaries were skillfully rendered in L. Kohl's etchings and A. Machek's lithographs and portraits. The Czech landscape received poetic treatment in the works of K. Postl, A. Kosárek, and A. Mánes. The genre scenes and still lifes of J. Navrátil are notable for their freedom and refined lightness of style. The common people, who became an important theme during the Revolution of 1848–49, were masterfully portrayed in the romantically inclined works of J. Mánes. In addition to poeticized scenes from folk life and generalized natural panoramas, Mánes produced portraits showing keen observation, as well as lyrical illustrations of folk songs. J. Čermák's works extolled the liberation struggle of the Slavic peoples. In the late 1850's and the 1860's democratic realism was represented by K. Purkyně's portraits and still lifes, executed in a vigorous and sensuous style.

In the last third of the 19th century the artists of the "National Theater generation," headed by the painter M. Aleš, a follower of J. Mánes, had a considerable influence on the development of Czech art. In his paintings of popular legends and events from national history and his illustrations to folk songs Aleš affirmed

democratic principles and the lyrical and epic trend in art. The works of other students of Mánes, notably F. Ženíšek and J. Tulka, as well as the historical compositions of V. Brožík, show the influence of academicism. Two other major painters of the late 19th century were J. Mařák, noted for his monumental epic landscapes, and A. Chittussi, who turned to plein air painting in the 1880's. J. V. Myslbek was the foremost sculptor of the late 19th century.

In the early 20th century, amid conflicting trends in art, a progressive school emerged to oppose the decadent tendencies. The leading landscape painters were Mařák's students F. Kaván, B. Dvořák, and A. Kalvoda. The impressionist A. Slavíček created generalized epic images of his native landscapes. A poetic lyricism infused the landscapes of A. Hudeček and the paintings of M. Jiránek. J. Úprka and L. Kuba painted picturesque scenes from peasant life. A critical view of society underlay K. Myslbek's severe, monumental pictures and etchings. Symbolist elements are present in J. Preisler's visionary canvases and murals, full of vague foreboding, and F. Kupka's compositions and caricatures. In M. Švabinský's pictures and engravings symbolism is combined with a strong faith in life. Graphic art reached a high level in the etchings of Z. Braunerová and T. F. Šimon. The prevailing *art nouveau* style was best expressed in the engravings of V. Preissig, the posters of A. Mucha and A. Hofbauer, and the book illustrations of J. Lada, A. Kašpar, and A. Šajner. The leading sculptors at the turn of the century were S. Sucharda, J. Mařatka, J. Štursa, O. Španiel, L. Šaloun, and F. Bílek.

The early 20th-century aspiration toward a synthesis of the arts gave rise to the creative cooperation of the architect J. Kotěra and the painter J. Preisler. Many artists, notably F. Bílek, A. Mucha, and S. Sucharda, devoted much attention to decorative applied art, chiefly glasswork, ceramics, and interior decoration. From around 1910 to 1920 Czech painters came under the influence of European avant-garde styles (fauvist and cubist paintings of B. Kubišta, E. Filla, V. Novák, and A. Procházka), although some artists sought to reinterpret such styles in a national spirit (painting and graphic art of V. Špála, J. Čapek, J. Zrzavý, and R. Kremlička). The painters V. Rabas, V. Rada, and V. Sedláček followed national artistic traditions.

The establishment of an independent bourgeois Czechoslovak state in 1918 stimulated a flowering of artistic culture, which was increasingly influenced by the communist and labor movement. A national functionalist school of architecture emerged in the 1920's and 1930's; its leading exponents were J. Gočár, K. Honzík, and J. Havlíček. Besides designing villas and public buildings (Gočár's structures in Hradec Králové), architects became involved in planning residential housing complexes using standard designs. One of the first cities to initiate such housing projects was Zlín, now Gottwaldov. Nevertheless, down to the mid-20th century most Czech cities retained their medieval appearance, while slums proliferated on the outskirts. Two notable achievements of the prewar years were the completion of the western part of the St. Vitus Cathedral in Prague (1929) and the construction of the National Liberation Monument on Vitkov Hill (begun 1929, architect J. Zázvorka).

In art, realistic and democratic tendencies were strengthened in the 1920's and 1930's through the clash of opposing views on the nature of art. Some avant-garde artists turned to the traditions of realism, as illustrated by the landscapes, still lifes, and genre paintings of V. Novák, O. Nejedlý, and O. Kubin. The folk aspect was strengthened in the work of J. Čapek, V. Špála, and J. Lada. In their landscapes and scenes from folk life V. Rabas, V. Rada, and V. Sedláček continued to develop the national traditions of realism. The "social" art that arose in the 1920's and 1930's truthfully depicted the life and struggle of the working class. The artists of this school—notably the painters K. Holan, P. Kotík, and M. Holý, the graphic artists V. Silovský, J. Rambousek, and K. Štika, and the sculptors K. Kotrba, K. Pokorný, J. Lauda, and O. Gutfreund—produced intensely dramatic works employing expressionist and primitivist techniques. Several artists close to the communist movement, such as K. Teige, F. Muzika, and J. Šíma, gravitated toward constructivism and "poetism."

The growing threat of fascism gave impetus to antifascist political satire, whose undisputed masters were F. Bidlo, A. Pelc, and J. Čapek. Social art found a brilliant exponent in K. Štěch, and the courage of the proletariat and the beauty of labor were affirmed in the works of K. Pokorný. A fresh approach to the homeland theme marked the landscapes and peasant scenes of V. Rabas, V. Rada, and B. Dvorský. In their antiwar and antifascist works, pervaded by a sense of tragedy, E. Filla, J. Čapek, V. Sychra, V. Tittelbach, and F. Muzika resorted to symbol and allegory and at times even a surrealist mask.

The progressive national traditions were carried on during the German occupation, when many artists died in concentration camps.

The liberation of Czechoslovakia from fascist oppression in 1945 and the victory of the people's democratic system opened up new opportunities for artistic development. Standard designs and industrial techniques were widely adopted in construction. In 1948 new residential districts with schools, hospitals, sports installations, and public centers were built in Prague, Gottwaldov, Horní Litvínov, Olomouc, Znojmo, and other cities. Hydroelectric power plants were built on the Labe and Vltava, and new cities, such as Mladá Boleslav, were founded. The brick apartment buildings erected in the early 1950's were decorated with national ornamental motifs. From the mid-1950's formally severe buildings were constructed using large blocks and panels, and perimetric planning was replaced by a freer layout. The public buildings of the 1960's, marked by rational simplicity and severe elegance of form, show a subtle appreciation of the expressive possibilities of such modern materials as glass, aluminum, and plastic. Since the early 1970's architects have been emphasizing plastic expressiveness and individuality in building design. A fine example of this trend is the Federal Assembly Building in Prague (1970–73, architect K. Práger).

After 1945 the painters and graphic artists E. Filla, J. Brož, Z. Seydl, A. Paderlík, V. Sedláček, and L. Šimák turned to antifascist themes, revolutionary history, and socialist construction. The sculptors V. Makovský, K. Lidický, K. Pokorný, J. Wagner, and J. Malejovský created victory monuments and works honoring the heroes of the Prague uprising, Soviet soldiers, and Czech cultural figures. The older generation of realistic artists, including M. Švabinský, V. Rabas, L. Kuba, V. Sedláček, J. Zrzavý, and V. Novák, embarked on a new fruitful period of activity. Monumental decorative art flourished in the mosaics of V. Sychra and M. Švabinský, the sgraffito of A. Zábranský, and the frescoes of V. Tittelbach. Book illustration was represented by K. Svolinský, C. Bouda, V. Fiala, A. Strnadel, F. Muzika, and O. Hlafsa. Among the finest achievements of those years were the thematic paintings of J. Brož, the poetic generalized landscapes of B. Dvorský, J. Slavíček, and F. Jiroudek, and the still lifes of A. Paderlík. Modern urban life and the world of technology were portrayed by F. Gross, J. Smetana, and K. Souček. Decorative applied art reached a high level in the artistic glasswork of J. Brychta and L. Smrčková, the fabrics of A. Kybal, the ceramics of O. Eckert, the medallions of K. Lidický, M. Knobloch, and Z. Kolařský, and the stage designs of F. Troester and J. Svoboda.

In the late 1950's and the 1960's the younger artists' concern with pressing contemporary themes was joined to a quest for new expressive artistic solutions and a predilection for symbolic and poetic imagery. Some artists were preoccupied with formal experimentation and followed Western neo-avant-garde trends.

The early 1970's saw a return to democratic and realistic traditions and to socialist ideals. In the 1970's events from revolutionary history were depicted in the monuments of J. Malejovský, M. Axman, J. Hana, and V. Dobrovolný and the paintings and graphic art of A. Zábranský, K. Souček, R. Kólař, and J. Brož.

I. L. MATSA (architecture from the ninth to 19th centuries) and E. K. VINOGRADOVA (art)

Music. Czech musical culture evolved out of the ritual folk songs and dances that developed among the Czechs through the ages and that were very different from the Gregorian chant that the Catholic clergy imposed from the ninth century. Among the oldest folk instruments were the bagpipe, the reed pipe (*fujara*), and the tambourine. Flutes and drums were introduced in the 11th century, and the zither, trumpet, kettledrum, harp, and psaltery came into use in the 13th century. In 1256 an organ was installed in one of Prague's cathedrals.

In the 13th century, anonymous authors composed mono-

phonic sacred songs, of which the most famous was "Saint Wenceslas." The melodies of such religious songs as "God the Almighty" and "Jesus Christ, Our Generous Lord," dating from the first half of the 14th century, eventually became folk melodies. From the 12th to the 14th century Christmas and Easter pageants were accompanied by solo and choral singing. Secular music began developing in the 13th century under the influence of the minnesingers. Over the next two centuries wandering musicians entertained audiences with religious and secular performances whose traditions, like those of sacred folk music, would survive down to the 19th century. The influence of *ars nova* spread to Czech music in the early 14th century. The 15th-century Hussite songs marked a flowering of Czech song culture. The melodies of such songs as "Arise, Arise, Great City of Prague" and "Those Who Are God's Warriors" were later used by the greatest Czech composers. Bohemian polyphonic music of the 16th century bore national traits derived from folk music. The leading composers of Bohemian Renaissance polyphonic music were A. Michna of Otradovic, V. Holan Rovenský (second half of the 17th century), J. Rychnovský, T. Turnovský, and K. Harant of Polžic.

After the Czech lands were absorbed into the Hapsburg Empire in 1526, many Czech composers emigrated to Russia, Poland, Italy, Germany, and other countries, whose musical culture they enriched with Czech traditions. Prominent among the Czech composers who worked abroad in the 17th and 18th centuries were J. D. Zelenka (Dresden), B. Černohorský (Padua), and J. V. Stamitz, F. X. Richter, and A. Filtz, who together formed the Mannheim school. Černohorský founded the 18th-century Czech polyphonic school, which included J. Zach, F. I. Tůma, J. N. Seger, and F. X. Brixi. These composers continued to develop the national traditions despite the artificial grafting of German culture. In the 18th century Prague, the "conservatory" of Europe, was the home of outstanding composers who influenced the development of West European music. V. F. Míča was one of the originators of the symphony genre, which was further developed by Stamitz. Operas were composed by J. Mysliveček, melodramas by J. Benda, and violin music by F. Benda. Working abroad in the late 18th and early 19th centuries, the Czech composers J. Mareš, P. Vranický, A. Vranický, J. L. Dusík, and A. Reicha did not lose touch with the folk music of their homeland; they introduced Czech folk melodies into classical European instrumental music. The development of Czech opera was stimulated by the founding in Prague of the Kotcu Theater (1737), Bohemia's first opera theater, and the national Nostitz Theater (1783), renamed the Estates Theater in 1797.

The emergence of a national school of classical music in the 19th century owed much to the educational activity of the "awakeners," who strengthened the national consciousness of the people and promoted their national culture. The national awakening is reflected in the work of F. Dušek, who initiated the Czech school of piano playing, J. J. Ryba, and V. J. Tomášek, whose student J. Voříšek expanded the genres of piano music. F. Škroup, who composed the first opera in Czech, *The Tinker* (staged 1826), and the patriotic song "Where Is My Home" (which was originally written for J. K. Tyl's play *Fidlovačka* and which later became the national anthem), prepared the ground for the operas of B. Smetana, the founder of Czech classical music.

Blending the traditions of national music with the highest achievements of world music in his operas *The Brandenburgers in Bohemia* (1863) and *Libuše* (1872, staged 1881) and in his symphonic cycle *My Country* (1874–79), Smetana evoked the heroes of Czech history, the natural beauty of his land, and scenes from folk life. As the principal conductor of the Provisional Theater in Prague, founded in 1862, and director of the Hlahol Pražský chorus and orchestra, organized in 1861, Smetana encouraged the development of national realistic art and strengthened the ties with Russian music by staging Russian operas. Czech music became world famous through the works of A. Dvořák, who composed ten operas (1870–1903), various works for chorus and orchestra, nine symphonies (1865–93), symphonic poems, such other orchestral works as the *Slavonic Dances* (1878–87) and *Slavonic Rhapsodies* (1878), a cello concerto (1895), and other well-known works. The Czech classical traditions were developed by Z. Fibich, who wrote dramatic and emotionally charged operas and melodramas.

The extremely personal style of L. Janáček marked a new phase in the development of Czech music. Working with a great variety of themes and genres, Janáček drew on Moravian folk music and sometimes chose subjects from Russian literature, as in his Slavonic rhapsody for orchestra *Taras Bulba* (1918) and his operas *Kát'a Kabanová* (based on A. N. Ostrovskii's play *The Thunderstorm*, 1921) and *From the House of the Dead* (after Dostoevsky, 1928). Other prominent composers of the late 19th and early 20th centuries were J. B. Foerster, Dvořák's pupils V. Novák and J. Suk, and Fibich's pupils K. Kovařovic and O. Ostrčil, both distinguished conductors at the National Theater.

Czech musicology, founded by O. Hostinský, has been strongly influenced by Z. Nejedlý, who championed realism in music in his publicistic and scholarly works. The founding in Prague of a conservatory (1811), an organ school (1831), the National Theater (1881), the Czech Quartet (1891), the Czech Philharmonic Society (1901), and other music organizations and schools contributed to a high level of musical performance. From the 1830's Bohemia produced many outstanding performers, among them the violinists J. Slavík, F. Laub, F. Ondříček, O. Ševčik, and J. Kubelík, the cellist G. Vigan, and the singers V. Heš, B. Benoni, J. Lev, J. Paleček, K. Čech, K. Burian, E. Destinová (Destinn), and B. Foersterová-Lautererová.

In the 1920's and 1930's, while composers of the older generation continued to develop the classical traditions and to favor operas based on national folk music, a modernist trend emphasizing formal experimentation emerged under the leadership of A. Hába, the inventor of the quarter-tone system. National music was popularized by the conductors O. Ostrčil and V. Talich and the musicologist V. Helfert. Both new and classical works were performed by the Prague Quartet (1920), the Ondříček Quartet, the Prague Wind Quintet (1928), and the various ensembles formed earlier. Antifascist and patriotic themes, recurrent from the mid-1930's, were brilliantly expressed in Ostrčil's opera *Honza's Kingdom* (1934), E. Schulhoff's *Symphony of Freedom* (1941), and B. Martinů's play for orchestra *Memorial to Lidice* (1943).

After the victory over fascism in 1945 musical life was invigorated by the founding of numerous music institutions (Academy of Arts in Prague, 1946) and performing groups and the holding of regular festivals (Prague Spring, from 1946). The general cultural revival that followed the triumph over reaction in Czechoslovakia in 1948, coinciding with the democratization of music and the affirmation of realism, brought forth optimistic compositions about the building of a new life, principally cantatas and mass songs. V. Dobiáš and E. Axman emerged as major composers, and Z. Nejedlý's articles influenced the development of music. B. Martinů, who did not lose touch with his homeland during his long stay abroad, held a prominent place in Czech music in the 1940's and 1950's, composing 15 operas, some of them on Russian subjects, ten ballets, symphonic works, concerti, and numerous instrumental chamber works. Among other prolific composers were K. Burian (eight operas, cantatas), J. Rídký (seven symphonies), and I. Krejči (operas, ballets, concerti).

Several gifted composers came to prominence in the 1960's and 1970's, notably J. Pauer (operas and ballets), V. Sommer (orchestral and other works), L. Železný, S. Havelka, and V. Kalabis (*Symphony of Peace*). The best-known performing groups—besides those founded before 1918—are the Smetana and Janáček string quartets, the Suk Trio, the Sluk Song and Dance Ensemble, and various choral groups (*see* CZECHOSLOVAKIA: Music).

N. A. SIMAKOVA

Theater. The Czech theater has its roots in ancient pagan rituals and in the peasant festivals of later times. The introduction of interludes into mystery plays in the 14th century signified a shift from religious subjects to everyday-life scenes. The first school drama to be written and performed in Czech was P. Kyrmezer's *Czech Comedy About a Rich Man and Lazarus*, published in 1566. The school theater fostered by the Jesuits stood in marked contrast to the amateur folk theater, which mirrored the struggle of the democratic strata of the population for national independence and their fight against social oppression.

The upsurge in the national liberation movement during the late 18th and first half of the 19th centuries—the period known as the national renaissance—heralded a new phase in the development of the Czech theater. The Czech "awakeners" revived the national traditions, developed a national dramaturgy, and trained actors. The Kotcu Theater, built in Prague in 1737, staged operas and later plays. The Nostitz Theater, founded in 1783 in Prague for the staging of German plays, began presenting plays in Czech in 1785. (In 1797 it was renamed the Estates Theater.) From 1786 to 1789 the Bouda (Patriotic) Theater in Prague staged plays in Czech four times a week.

Performances in Czech were banned in 1806, and Prague's company of Czech actors, which had been playing in various buildings after 1789, disbanded in 1811. In 1824 the Estates Theater began giving regular performances of Czech plays, directed by J. N. Štěpánek and with B. Allramová, J. Grabinger, and V. Šmiller playing the leading roles. When performances in Czech were discontinued at the theater in 1834, the dramatist J. K. Tyl organized the theater's Czech actors as an amateur company calling itself the Kajetán Theater, which existed until 1837.

Under pressure from the progressive intelligentsia, the Estates Theater, now under the direction of Tyl, once again began staging Czech plays in 1846. By this time the stage had become more professional, and the national repertoire was expanding. The leading exponent of romantic theater was the actor, dramatist, and prominent man of the theater J. Kolár. Founded in 1845, the Society for the Creation of a National Czech Theater for many years collected money for the construction of a theater building. The Provisional Theater, which operated in Prague from 1862 to 1883 and which had both an opera and an acting company, attracted the best performers, notably K. Šimanovský, O. Sklenářová-Malá, F. Kolár, and J. Mošna, and the foremost Czech directors, namely J. Kolár and E. Chvalovský. The National Theater, which had drama, opera, and ballet companies, was built in Prague in 1883 with funds collected from the public. The work of the Provisional Theater and the opening of the National Theater stimulated the formation of touring theaters in provincial towns, including Plzeň (1865) and Brno (1884).

Despite the appearance of various artistic trends in the late 19th and early 20th centuries, realism prevailed in the theater, largely owing to the fine acting of Kvapilová, E. Vojan, J. Mošna, J. Šmaha, and M. Hübnerová. The performances given by the Moscow Art Theater in Bohemia in 1906 influenced the development of the Czech realist school.

From the moment the National Theater opened, the progressive segment of the public urged the democratization of the theater and the establishment of close ties with the working-class theatergoer. Professional actors were able to assist workers' drama groups through the Union of Workers' Amateur Theater Activity, organized in 1911. The development of the Czech theater in the bourgeois Czechoslovak republic, founded in 1918, mirrored all the stages of a bitter class struggle. The founding of the Communist Party of Czechoslovakia in 1921 contributed to the spread of socialist ideas in the theater milieu and to the strengthening of contacts with the Slovak theater. Of great importance was the work of J. Fučík, M. Majerová, K. Konrád, B. Václavek, and Z. Nejedlý.

Disregarding official policy, the country's progressive theater men staged antibourgeois plays. The National Theater produced K. Čapek's *The Insect Comedy* (1922, 1926, and 1932), *The White Plague* (1937), and *Mother* (1938) and F. Šalda's *The Child*. New professional and semiprofessional revolutionary theaters were organized. At the Liberated Theater, founded in 1925, the director J. Honzl staged antibourgeois political revues written and performed by the actors J. Voskovec and J. Werich, with music by J. Ježek. The D-34 Theater was founded in 1933 by E. F. Burian, who drew on folklore and the experience of the Soviet theater. Czech theaters staged successful productions of such Soviet plays as M. Gorky's *Egor Bulychov* (D-34 Theater) and *Vassa Zheleznova* (National Theater in Prague), an adaptation of M. A. Sholokhov's *Virgin Soil Upturned* (Vinohrady Theater in Prague), and V. V. Vishnevskii's *An Optimistic Tragedy* (Municipal Theater in Olomouc).

An acting style developed that strove for subtle psychological portrayal and stressed rhythmic movement and external characterization. Its leading exponents were V. Vydra, Z. Baldová, J. Průcha, L. Dostálová, O. Scheinpflugová, and Z. Štepanek. The emergence of a new generation of gifted stage designers, among them V. Hofman, F. Troester, F. Kysela, F. Zelenka, J. Čapek, and M. Kouřil, contributed to the theatrical revival.

After the liberation of Czechoslovakia from the fascist occupation in 1945, the Czech theater took an active part in developing a socialist culture. The government abolished private theaters and enacted the Theater Law in 1948. Among the new theaters founded in the 1940's and 1950's for the ideological education of the working people were the Realist Theater (later the Nejedlý Theater) in Prague and the Workers' Theater in Gottwaldov. Also founded were the Academy of Arts, the Disk Theater Workshop, and the Union of Creative Workers in the Theater (1957). The most famous of the experimental "theaters of miniatures" that sprang up in the 1960's and 1970's are the Zábradlí (Balustrade), Semafor, and Rococo in Prague and the Evening Brno. The achievements of the contemporary Czech theater owe much to the skillful directing of K. Palouš, E. Sokolovský, Z. Míka, Z. Kaloč, J. Kačer, and P. Scherhaufer, the splendid acting of V. Záborský, J. Petrovická, M. Růžek, J. Švorcová, H. Vranová, and V. Šmeral, and the fine stage designs of J. Svoboda, O. Šimáček, and J. Sládek.

CZECH UPRISING OF 1547, the first large-scale uprising in the Czech lands against Hapsburg rule.

The uprising was provoked by heavy taxation, religious persecution, and the growing power of the German element in the country. Its immediate cause was an attempt by the Hapsburg king Ferdinand I to involve the Czech estates in the war with the Schmalkaldic League. The uprising was incited by the royal cities (headed by Prague), which were joined by the minor and middle nobility and landowners.

The Diet that convened in Prague in March confronted the king with the demands of the estates, set forth in 57 articles providing for regular meetings of the Diet, the Diet's right to elect the king, and other prerogatives. The Diet also elected an administrator for the kingdom and a commander in chief from among the representatives of the estates. Ferdinand responded by besieging Prague in July. Disagreements among the insurgents made it easier to crush the uprising. The Bloody Diet, convened in August, consolidated the victory of the Hapsburgs. Four of the uprising's leaders were executed; the royal cities lost their privileges and paid an indemnity; and the Hapsburgs gained the right to convene the Diet and appoint higher officials. [29–526–1]

CZECH UPRISING OF 1618–20, an anti-Hapsburg uprising of the Czech estates that heralded the Thirty Years' War (1618–48).

The causes of the uprising lay in the Hapsburgs' encroachment, intensified in 1617 and 1618, on the political and religious rights of the Czech lands, which still enjoyed a measure of independence within the Hapsburg monarchy. The uprising was sparked by the defenestration on May 23, 1618, of the Hapsburg vicegerents in the Czech lands, the Catholic landowners J. Martinic and V. Slavata, who were thrown from a window of the Pražský Hrad.

Although the uprising was headed by the great feudal lords, an important role in it was played by the lesser nobility, whose demands figured prominently in the insurgents' program, adopted by the Diet in July 1619. The Hundred Articles of the Act of Confederation, as the program was called, reaffirmed the elective nature of the Czech crown and called for the abrogation of all the Hapsburgs' anti-Protestant decrees. After the death of Emperor Matthias, the Czech estates refused to recognize his successor, Ferdinand II, and in August 1619 elected to the Bohemian throne Frederick V of the Palatinate, the head of the Protestant Union.

Initially, the army of the Czech estates, commanded by J. Thurn, and the mercenary army led by E. Mansfeld dealt a series of defeats to the imperial troops. Twice the insurgent armies besieged Vienna (in June and in October–December 1619) without taking the city. Meanwhile, Ferdinand II concluded a military alliance with the Catholic League and received the support of the pope and Spain. The Protestant Union virtually abandoned the Czech lands to their fate after reaching an agreement with the Catholic League in July 1620. Within Bohemia, the social base of support for the uprising was eroded by the policies of the Czech feudal estates, which ignored the interests of the townspeople and especially those of the peasants, who were rebelling and demanding the abolition of serfdom.

At the decisive battle of the White Mountain (Bílá Hora) on Nov. 8, 1620, the Czech forces were crushed. Frederick of the Palatinate fled Prague. Twenty-seven of the uprising's leaders were executed, and the Czech lands were completely subjugated by the Hapsburgs, losing their national independence for three centuries. The suppression of the uprising, by shifting the balance of power in Europe, ensured the defeat of the anti-Hapsburg coalition in the first, or Czech, phase of the Thirty Years' War. [29–526–2]

CZECH UPRISING OF 1775, the largest antifeudal peasant uprising in Bohemia and Moravia from the 16th to 18th centuries.

Although a "peasant governorship" had been established in the village of Rtyně on the Náchod estate to prepare for and direct the uprising and to work out a plan of action, the uprising began spontaneously in March, spreading outward from the Hradec and Budějovice regions. Peasants refused to perform the *corvée* and sacked and burned estates. The operations of the peasant detachments were not coordinated, however. On March 25 part of the insurgent forces was defeated by imperial troops near the town of Chlumec; the detachments that managed to reach Prague were dispersed. Many rebels were thrown into prison, and several were executed. In June the uprising flared up again, encompassing most of Bohemia and Moravia. At the end of August, however, it was suppressed by the army. In spite of its defeat, the uprising, taking place during a crisis in the *corvée* system, obliged the government to promulgate the Corvée Patent of 1775, which reduced labor services.

CZEKANOWSKI, JAN. Born Oct. 6, 1882, in Głuchów; died July 20, 1965, in Szczecin. Polish anthropologist and ethnologist. Member of the Polish Academy of Sciences (1924).

Czekanowski studied in Warsaw and Libau (now Liepāja, Latvian SSR) and at the University of Zürich in Switzerland. He received the degree of doctor of sciences in 1906. From 1906 to 1910, Czekanowski was on the staff of the Museum of Ethnology in Berlin; he spent the years 1907 to 1909 on a German expedition to Central Africa. He was a curator of the Museum of Anthropology and Ethnography of the Imperial St. Petersburg Academy of Sciences from 1911 to 1913 and a professor of anthropology at the University of Lwów (L'vov) from 1913 to 1941. Between 1945 and 1949 he taught at the Catholic University of Lublin. He became a professor of anthropology in Poznań in 1946.

Czekanowski's principal works deal with the ethnic composition of Europe and Central Africa, the anthropology of Poland and the eastern Baltic regions, the analysis of races, and the question of the origin of the Slavs and other Central European peoples. Czekanowski was mistaken in some of his ideas about race.

CZELADŹ, a city in Poland, in Katowice Województwo, in the Upper Silesian conurbation. Population, 34,700 (1976). Economic activities include the mining of hard coal and the production of porcelain and faience. [29–169–2]

CZERNIN, OTTOKAR. Born Sept. 26, 1872, in Dymokury, near Poděbrady, in what is now Czechoslovakia; died Apr. 4, 1932, in Vienna. Austrian political figure; count.

In 1903, Czernin was elected a deputy to the Bohemian diet from the chauvinistic German Party. In 1912 he became a member of the Austro-Hungarian House of Lords. From December 1916 to April 1918 he served as minister of foreign affairs. Recognizing the profound crisis of the Hapsburg monarchy, Czernin sought a compromise peace treaty with the Entente. For this reason he conducted secret negotiations with France; news of the negotiations, however, reached the press and led to his resignation. From 1920 to 1923, Czernin was a member of the National Council of Austria. [29–251–1]

CZERNY, KARL. Born Feb. 20, 1791, in Vienna; died there July 15, 1857. Austrian pianist, teacher, and composer. Czech by nationality.

Czerny was initially taught by his father, Wenzel Czerny; from 1801 to 1803 he studied with L. van Beethoven. He established the Viennese school of piano playing of the first half of the 19th century. His pupils included F. Liszt, T. Leschetizky, T. Döhler, T. Kullak, and A. de Belleville-Oury.

Czerny is the author of more than 1,000 compositions, including symphonies and religious and chamber music. The bulk of his oeuvre consists of works for the piano, among them arrangements and transcriptions of compositions by other composers. His numerous exercises are still used in piano teaching. Czerny's compositions and his approach to pianistic technique reflect both

classical and romantic influences and a striving for a lyric and expressive style of playing.

CZERSKI, JAN (also Ivan Dement'evich Cherskii). Born May 3 (15), 1845, on the estate of Swolno, Drissa District, Vil'na Province; died June 25 (July 7), 1892. Geologist, paleontologist, and geographer; explorer of Siberia. By nationality, a Pole.

Czerski was conscripted into the army and sent to Omsk for his role in the Polish uprising of 1863–64. Under the influence of G. N. Potanin, he undertook geological and paleontological research in the Omsk region. In 1869 he was discharged from military service because of illness. In 1871 he moved to Irkutsk. From 1873 to 1876, Czerski studied the Saians, the Saian region, and the Angara region. Between 1877 and 1880, he investigated the geological structure of the shores of Lake Baikal. In 1881 and 1882, he explored the Selenga River basin and the Nizhniaia Tunguska River.

In 1878, Czerski introduced the concept of the evolution of relief. He proposed one of the first paleotectonic schemes for Siberia; Czerski's scheme was used and further developed by E. Suess in his work *The Face of the Earth*.

In 1885, Czerski was pardoned and, at the invitation of the Imperial St. Petersburg Academy of Sciences, moved to St. Petersburg. En route to the capital, he carried out geological research along the postal route from Irkutsk to the Urals, making excursions to the Padun Rapids of the Angara and to Minusinsk. In 1891, he went on an expedition to the region of the Kolyma and Indigirka rivers. He died on the lower Kolyma.

A mountain region (the Cherskii Range) in the Yakut ASSR and Magadan Oblast and the Cherskii Range in Transbaikalia have been named for Czerski.

CZERWONY SZTANDAR (Red Banner), a Polish-language republic newspaper of the Lithuanian SSR. Founded in 1953, it is published in Vilnius six times a week. Circulation, 46,600 (1976). [29–183–1]

CZĘSTOCHOWA, a city in southern Poland. Population, 203,000 (1976). The capital of Częstochowa Województwo, Częestochowa is a transportation junction. It has large linen and woolen mills and an iron and steel plant. It also manufactures glass, matches, building materials, and food products. Częstochowa is the center of an iron-mining region. [29–175–2]

CZĘSTOCHOWA WOJEWÓDZTWO, an administrative and territorial unit in southern Poland. Formed in 1975. Area, 6,200 sq km. Population, 731,000 (1975), of which 45 percent is urban. The capital is the city of Częstochowa.

The economy of Częstochowa Województwo is based on industry and agriculture. The *województwo* has metallurgical, machine-building, metalworking, textile, food-processing, cement, by-product coke, and building-materials industries. Iron ore is mined. Plowland makes up 46 percent of the total area, and forests account for 32 percent. The *województwo* has approximately 250,000 head of beef and dairy cattle and approximately 300,000 swine. The principal crops are rye and potatoes. [29–175–3]

CZESZKO, BOHDAN. Born Apr. 1, 1923, in Warsaw. Polish writer.

Czeszko fought in the ranks of the People's Army against fascism and took part in the Warsaw Uprising of 1944. Between 1947 and 1951 he studied at the Academy of Fine Arts in Warsaw. His work was first published in 1946. He has produced collections of short stories and journalistic pieces, including *Moscow, Volga, Baku* (1956). Particularly well known are his autobiographical novella *Generation* (1951), which depicts the struggle of working-class youth against the Hitlerites, and his novella *Requiem* (1961), which portrays the everyday life and defeat of a Polish Army unit in 1945. Czeszko's prose is characterized by a contrast between idealized and naturalistic description and by the use of colloquial language.

Czeszko became a deputy to the Sejm in 1965. He was awarded the State Prize of the Polish People's Republic in 1952, 1964, and 1976.

CZYNSZ, in feudal Polish lands, a quitrent rendered in cash or kind by feudally dependent peasants to their lord; equivalent to the German *Zins*, the French *cens*,and the English census. Peasants who paid a *czynsz* were called *czynszownice*. These peasants usually held a hereditary piece of land, in exchange for which they fulfilled certain obligations to the feudal lord; among these obligations, the cash payment of the *czynsz* gradually assumed the greatest importance. [29–612–3]

DANDY ROLL, a skeleton roll on a paper machine, consisting of a wire frame wrapped with netting. It is designed to level the surface of the paper, improve the paper's structure and uniformity, and put watermarks on the paper web.

Ivanov, S. N. *Tekhnologiia bumagi*, 2nd ed. Moscow. [29–1677–3]

DEMOLITION BLOCK, a compact explosive charge used in demolition work. [29–920–3]

DERMOPTERA (gliding or flying lemurs), an order of mammals. The body length is about 40 cm, and the tail length is about 25 cm. The body weight is 1–1.7 kg. The limbs and tail are joined by a broad fur-covered membrane, with the help of which the animal can glide from tree to tree. Gliding lemurs are found in the Philippines and southern Indochina and on most islands of the Malay Archipelago. The forest-dwelling arboreal animals are nocturnal and herbivorous. The female gives birth to one offspring, occasionally two.

The single genus, *Cynocephalus*, embraces two species: the Phillipine gliding lemur (*C. volans*) and the Malayan gliding lemur (*C. variegatus*). Because the order combines characteristics of insectivores, chiropterans, and prosimians, it is difficult to classify. On some islands the animals are hunted for their meat and fur. [29–1147–1]

DEVIL (Russian, *chert, bes*), in religious and superstitious representations, an evil spirit, unclean force, or supernatural being. Devils are described in folklore and in works by A. S. Pushkin, N. V. Gogol, F. M. Dostoevsky, and other writers. [29–326–2]

DIASPIDIDAE, a family of homopteran insects of the suborder Coccoidea. The insects measure as much as 2 mm in length and

have a waxy carapace. Sexual dimorphism is marked. The females lack wings and legs, while the males, which are smaller than the females, have one pair of wings, normally developed extremities, and reduced mouth organs. The larvae and adult females suck the juices of plants.

The family embraces approximately 1,300 species, which are distributed throughout the globe, mainly in warm latitudes. The USSR has about 130 species. The Diaspididae live in trees and shrubs and occasionally on herbaceous plants. Many species are pests of citrus, apple, plum, peach, and mulberry trees. [29–1612–1]

DJAZIRAH DOBERAI (also Vogelkop), a peninsula in the northwestern part of the island of New Guinea, in Indonesia. The peninsula is about 350 km long and has a maximum width of 200 km; it is connected to the mainland by an isthmus with a width of about 20 km. In the north and east are mountains rising to an elevation of about 3,100 m at Mount Gwamongga; in the south lies a lowland. The peninsula has tropical rain forests that become quite swampy in the south. The local population engages in tropical land cultivation. There are petroleum deposits at Klamono, Mogoi, and Wasian. The port of Sorong is located on the western coast of the peninsula. [29–174–6]

DOWEL, an inserted pin for connecting parts in joinery. It consists of a wooden or plastic cylinder 6–20 mm in diameter and 25–160 mm long. The ends are slightly beveled, and the sides are fluted to allow air to escape when the dowel is driven into a hole. The dowel is smeared with glue before insertion. Dowel joints are more economical than mortise joints. [29–1253–2]

DOWEL-MAKING MACHINE, a woodworking machine for producing wooden dowels. It cuts a square or round workpiece to the necessary diameter, bevels the ends of the dowel, and cuts longitudinal grooves on the cylindrical surface. The machine can produce up to 2,000 dowels per hour. [29–1253–3]

DRAFTING AND DESIGNING EQUIPMENT, the instruments, attachments, and other equipment used to make mechanical drawings. The principal articles of drafting and designing equipment are a drawing board for arranging and securing the drawings, a stand on which the drawing board is mounted, a drafting machine, drawing instruments, and auxiliary equipment.

The drawing board has a flat surface whose dimensions exceed those of the drawing by 100–200 mm. Drawing boards are usually made of linden laths; plywood (for school drawing boards) with an oak or beech frame; glass; plastic; or chipboard with a plastic surface. Drawing boards made from a transparent material and equipped with a light fixture underneath facilitate tracing and copying. Boards made from combinations of materials are also used; one half is made from organic glass with scale grids and regulated illumination from beneath, and the other half is made of wood or laminated chipboard. Portable boards are 300 × 500 mm, designer's boards are 1,000 × 1,350 mm, and boards for particularly large drawings are 1,350 × 5,000 mm. The drawings are secured to the board by tacks or tape.

A stand is used to hold the drawing board in a convenient position for work—at any angle and 300–700 mm above the floor. Fixed stands may have one or two columns. Single-column stands can be rotated 360° about the vertical axis. Stands for designer's drawing boards have a system for balancing the board (for example, by means of weights or springs) or a device for raising, lowering, and turning the board (usually with a mechanical or hydraulic drive).

A drafting machine is a precision device that makes it possible to draw straight lines of a given length at any angle in the plane of the drawing board. Two types are used: the pantograph, which consists of a system of levers hinged together in the shape of a parallelogram, and the coordinate type, which has two mutually perpendicular bars along which carriages are moved. The parallelogram mechanism (in the first type) and one of the carriages (in the second) have protractor heads with two mutually perpendicular, scaled straightedges. The straightedges may have different scales and lengths; the horizontal one is usually 500 mm long, and the vertical 300 mm. The straightedges are made from metal-reinforced plastic or a thin-walled steel section. The protractor head provides an accuracy of up to 5′ (with continuous settings or detents for increments of 15°). The head has two scales for reading (positive and negative) and a device to shift the scales in order to construct projections at an angle. The machine has a lock mechanism to set the position of the head and turn it 90° from the plane of the board, attachments to align the straightedges, parallel rules for hatching, and lettering devices.

Drawing instruments consist of sets of marking and drawing compasses and outside calipers of various types and sizes, in addition to (when necessary) auxiliary attachments, ruling pens and holders, and the like. The range of radii inscribed with the various types of compasses is generally 0.5–300 mm or wider. Sets of drawing instruments also include cases for storing compasses, leads, and spare pen points, often made in the form of a screwdriver, point holder, or extension device. Brass buttons with a point and an indentation for the support leg of a compass are used to protect the surface of drawing boards and paper when inscribing concentric circles. Brass is used to make the most accurate instruments for critical work; less accurate instruments are made of steel.

A set of drawing instruments often includes devices for sharpening pencils and removing lines drawn by mistake. Leads, except those of calibrated thickness, are sharpened by manual or electric sharpeners. Pencil lines are removed from drawings with rubber erasers. For the correction of drawings executed in certain paste-like media that are absorbed deep into the paper, a white paste is used to cover up the unwanted elements of the drawing. The india and regular inks used in calibrated pens with reservoirs can be removed from a drawing with erasers that have a microporous structure; in the pores of the erasers is an india ink solvent, which dissolves the ink and removes it at the same time.

Auxiliary equipment is used to draw characters, letters, or numerals. Manual writing devices include various types of pencils, ball-point pens, soft-tip pens, and calibrated pens with ink reservoirs (in Russian, *rapidografy*). Mechanical pencils with graphite cores and graphite-containing pastes in metallic, calibrated tube holders are widely used; they do not need sharpening and allow one to draw lines 0.2–1 mm thick. Lines of varying thickness are also obtained with ball-point pens. Soft-tip pens produce lines of consistent width. They have cores made of glass fiber, polyamide (for example, *kapron*), or ceramic material. When drawings are made with india or special inks, calibrated pens with ink reservoirs are used; they draw lines 0.1–2.5 mm wide and are manufactured in seven or eight standard sizes.

Various types of rulers (including T-squares) and triangles are used in making mechanical drawings. Among the devices used to speed up drafting work are templates (for writing in inscriptions and standard designations and drawing standard parts), french curves (for drawing complex curved and connecting lines), and decals, which are small, dry, transferable illustrations of often-used fasteners, standardized circuits, and fixture representations. Mechanized means, such as typewriters, are also used to print letters, numerals, and standard symbols. The use of the templates, the simplified representation of often-used elements, and the pasting up of drawings from standard elements are other techniques designed to reduce the volume of drafting work.

The use of computer-controlled automated equipment improves the quality and increases the productivity of design work. Such equipment includes board- and roll-type graph-plotting devices, scanning and discrete-processing graphic copiers, and graphic displays. Drawings and other documents can be executed on paper, microfiche, or microfilm; the information they contain can also be converted into digital form and be recorded on machine information carriers, such as punched cards or magnetic tape, for subsequent computer processing. The use of automated equipment in drafting and design work speeds up the design process.

Drafting and designing equipment and supplementary fittings and devices are used in organizing the designer's work position. The designer keeps the necessary reference works, templates, and a calculator at a writing desk used for making calculations. Drawings and auxiliary materials, calibrated pens, and other items are kept on a preparation table, which is usually set be-

tween the writing desk and the drawing board stand; drawing instruments and various reference materials are kept in the drawers of the table or in roll-out stands. Work positions equipped with a display and a graph-plotting device are usually combined into complexes for use by groups of designers working together.

DRILL HOLE (*shpur*), a man-made cylindrical cavity in a solid medium, such as rock or concrete, with a diameter up to 75 mm and a depth up to 5 m. Drill holes are used to place blasting charges, to anchor supports, and to force water or cement into the surrounding rock. The holes are drilled with hammer drills, electric drills, and other light-duty drilling machines. [29–1410–6]

DROSS, an intermediate product obtained from the liquation separation of heavy nonferrous metals with low melting points: lead, bismuth, and tin. As the metals are cooled during the refining process, impurities of low solubility, such as copper and iron, crystallize. Denser and possessed of a higher melting point than the metal being refined, the impurities (in the elemental state or in compounds) float to the surface of the bath as solids to form dross. Additives of sulfur or carbon are sometimes introduced into the metal being refined in order to remove a higher percentage of impurities. The deeper the cooled metal, the more complete the crystallization and purification; however, there is also an increase in dross yield and in the amount of refined metal found in the dross.

Dross is removed from the surface of the liquid bath with a skimmer. The liquid metal entrained mechanically with the dross drains into the bath. Dross is highly complex with respect to its chemical and phase composition; the refined metal constitutes its base. The dross obtained in the refining of lead is reprocessed by smelting in a reverberatory or electric furnace with the addition of a sulfidizing agent and fluxes. The smelted lead is returned to the primary production cycle, and the matte and speiss produced are sent to copper mills. The dross obtained in the refining of bismuth and tin is recycled.

DRYOPTERIS, a genus of ferns of the family Aspidiaceae. There are about 150 species, distributed in the temperate zone of Eurasia and North America and, to a lesser extent, in the tropical regions of Asia, Africa, and South America. The USSR has about 15 species. Especially widely distributed is the male fern (*D. filix-mas*). *D. carthusiana* (formerly *D. spinulosa*) is found in damp, mossy forests of the European USSR, the Caucasus, and Siberia. Both species are used medicinally as anthelmintics. *D. fragrans* grows on cliffs and slopes of the northern European USSR, in Siberia, and in the Far East; *D. cristata* grows in humid regions and swamps in the European USSR and Western Siberia. [29–1612–2]

DUFF (Russian, *shtyb*), particles of hard coal less than 6 mm in size. [29–1508–1]

DUNLIN (*Calidris alpina*), also red-backed sandpiper, a bird of the family Charadriidae of the suborder Limicolae. The body length is about 20 cm. The upper parts are reddish brown, and underparts are dark. The dunlin is distributed in the tundras of Eurasia and North America, as well as along the shores of the Baltic and North seas. It is a migratory bird. Unmated birds roam the steppes of Western Siberia and Kazakhstan in the summer. The nests are on the ground. The clutch contains four eggs, which are incubated by both the male and female for 21 to 22 days. The diet consists of small invertebrates. [29–287–1]

EA, one of the three great gods of Assyro-Babylonian religion and mythology, the other two being Enlil and Anu. Among the Sumerians, Ea was known as Enki. He was the deity of the world ocean and of the fresh water beneath the ground. He was also the god of wisdom. Ea was considered benevolent. [29–1627–2]

EAKINS, THOMAS. Born July 25, 1844, in Philadelphia; died there June 25, 1916. American painter.

Eakins studied at the Pennsylvania Academy of the Fine Arts in Philadelphia, and from 1866 to 1869 he studied at the Ecole des Beaux-Arts in Paris. Eakins is the greatest American realist painter. He introduced into American painting themes from the life of the big city as well as an interest in various occupations, in people involved in art and science, and in sport, as seen in *Max Schmitt in a Single Scull* and *The Thinker* (1871 and 1900, respectively; both Metropolitan Museum of Art, New York) and in *The Surgical Clinic of Professor Gross* (1875, Jefferson Medical College, Philadelphia). Eakins combined strict objectivity and liveliness in depicting nature and the effects of light with profound psychological characterization (the portrait *Walt Whitman*, 1887, Pennsylvania Academy of Fine Arts).

EANNATUM. Ruler of the state of Lagash (c. 2450–2425 B.C.).

Various economic and legal documents from the period of Eannatum's rule have been preserved; some inscriptions on contemporary buildings have also survived. Through victories over the rulers of neighboring city-states in Sumer and Elam, Eannatum extended the boundaries of his state from the city of Ur to the city of Kish. His victory over Ush, the ruler of the city of Umma, is depicted on the famous Stela of the Vultures; Eannatum was fighting Ush for control of the region of Gu-eden, which bordered on Lagash.

EBBINGHAUS, HERMANN. Born Jan. 24, 1850, in Barmen; died Feb. 26, 1909, in Halle. German psychologist. Proponent of associationism.

Ebbinghaus was a professor at the University of Breslau from 1894 to 1905 and the University of Halle from 1905 to 1909. He founded, with A. König, the journal *Zeitschrift für Psychologie und Physiologie der Sinnesorgane*, which brought together psychologists who did not belong to the school of W. Wundt. Ebbinghaus initiated the experimental study of the higher mental functions, especially memory.

In his work *Memory* (1885), Ebbinghaus demonstrated that the process of memorization is influenced by the number of items to be memorized, the number of times the items are repeated, and the strength of the associations between the items, which is inversely proportional to the distance between them; his "forgetting curve" related forgetting to the passage of time. He developed a test to determine degrees of mental development. Ebbinghaus' textbooks on psychology have been reprinted many times.

EBEKO, an active volcano in the northern part of the island of Paramushir, one of the northern Kuril Islands. The volcano, which rises to an elevation of 1,138 m, has three craters, each with a diameter of 250–350 m. The craters contain lakes, thermal springs, and solfataras. The volcano is composed of andesites and basalts. Eruptions occurred in 1793, 1859, 1934–35, 1963, and 1967. [29–1628–1]

EBENACEAE, a family of dicotyledonous trees and shrubs. The leaves are usually alternate and entire. The regular flowers are

for the most part unisexual and three- to seven-parted. The fruit most often is a berry. There are about 450 species, making up five to seven genera. The plants occur mainly in the tropics and subtropics. In the USSR species of the largest genus—*Diospyros* (persimmon)—grow in the Caucasus. Many Ebenaceae yield valuable lumber (ebony) and edible fruit. [29–1629–1]

EBERS, GEORG. Born Mar. 1, 1837, in Berlin; died Aug. 7, 1898, in Tutzing, Bavaria. German Egyptologist.

Ebers was a professor at the universities of Jena (1865–70) and Leipzig (1870–89). While traveling in Egypt in 1872–73, he acquired the most extensive (known up to that time) ancient Egyptian medical treatise, which he published in 1875 and which has become known as the Ebers Papyrus. Ebers gained fame for his illustrated, popular descriptions of ancient and modern Egypt and particularly for his historical novels drawn from the life of ancient and Greco-Roman Egypt and medieval Germany, most of which were translated into Russian, including *An Egyptian Princess* (1883 and 1913), *Uarda* (1892), and *The Burgomaster's Wife* (1882). These novels quite accurately depict details of everyday life and mores, but they seldom accurately interpret historical events or truthfully portray historical figures.

EBERSWALDE (also Eberswalde-Finow), a city in the German Democratic Republic, in Frankfurt District, on the Finow Canal. Population, 47,200 (1975). Eberswalde manufactures crane equipment, rolled steel, ship fittings, chemicals, and paper. [29–1630–1]

EBERT, FRIEDRICH. Born Feb. 4, 1871, in Heidelberg; died Feb. 28, 1925, in Berlin. German political and state figure. One of the right-wing leaders of the German Social Democratic movement.

Ebert was a saddler by trade. He became a member of the Social Democratic Party of Germany (SDPG) in 1889. In 1905 he was elected to the administrative board of the SDPG, and in 1913 he became one of the chairmen of the board. In 1912, Ebert was elected to the Reichstag, and in 1916 he became the leader of the Reichstag's Social Democratic faction. During World War I, he held socialist and chauvinistic views.

On Nov. 9, 1918, during the Revolution of November 1918, Ebert accepted the position of chancellor from Prince Max of Baden. On November 10 he became cochairman of the provisional government, which was called the Council of People's Commissioners. On the same day, he concluded a secret agreement with members of the supreme military command concerning the introduction of military units into Berlin in order to suppress the revolution. In January 1919 the Ebert-Scheidemann government suppressed a revolutionary demonstration by the Berlin proletariat.

In February 1919, Ebert was elected president of the Weimar Republic. [29–1630–3]

EBERT, FRIEDRICH. Born Sept. 12, 1894, in Bremen. Party and state figure of the German Democratic Republic (GDR). Son of F. Ebert.

Ebert joined the Social Democratic Party of Germany (SDPG) in 1913 and was editor of a number of Social Democratic newspapers. From 1928 to 1933 he served as a deputy to the Reichstag. After the establishment of the fascist dictatorship in 1933 he carried on illegal antifascist work; as a result he was arrested and imprisoned in a concentration camp. In 1945 and 1946, Ebert served as chairman of the administrative board of the SDPG organization in Brandenburg.

From 1946 to 1948, Ebert served as chairman of the Brandenburg organization of the Socialist Unity Party of Germany (SED) and president of the *Landtag* of Brandenburg. In 1946 he became a member of the Central Board (later the Central Committee) of the SED, and in 1949 he was named a member of the Politburo of the Central Committee. From 1948 to 1967, Ebert was *Oberbürgermeister* (lord mayor) of Berlin. In 1949 he became a deputy to the People's Chamber of the GDR; from 1950 to 1963 he served as deputy chairman of the body, and in 1971 he was again named deputy chairman. In 1960 he became a member of the Council of State of the GDR, and in 1971 he became the council's deputy chairman. From 1949 to 1958 he served as president of the Society for German-Soviet Friendship.

Ebert has been named a Hero of Labor of the GDR twice. Among the orders awarded to him by the GDR are several Orders of Karl Marx. Ebert has also been awarded Soviet orders, including the Order of Lenin and the Order of Friendship of Peoples. [29–1630–4]

EBERT, MAX. Born Sept. 4, 1879, in Stendal; died Nov. 15, 1929, in Berlin. German archaeologist.

In 1922, Ebert became a professor at the University of Königsberg. He was a specialist on the archaeology of the Baltic region and of the southern part of Eastern Europe. Ebert published the multivolume archaeological *Dictionary of Prehistory* (vols. 1–15, 1924–32).

EBI NOR (also Ebi Nur), a brackish salt closed lake in northwestern China, the largest lake on the Dzungarian Plain. Ebi Nor is situated near the southern entrance to the Dzungarian Gates, at an elevation of 189 m. It covers an area of 1,070 sq km, although at times it shrinks to approximately 800 sq km, dividing into two bodies of water. The shores are low. Depths reach 15 m. Three main rivers flow into the lake: the Dzhergalan, Ching, and Boro-Tala.

The water level varies considerably from year to year, sometimes by as much as 5 m. On the whole the lake is in the process of shrinking; its shore terraces are situated at an elevation of 50 m. The lake freezes in the winter. [29–1631–1]

EBNER-ESCHENBACH, MARIE VON. Born Sept. 13, 1830, in Zdislavič Castle, Moravia; died Mar. 12, 1916, in Vienna. Austrian writer; baroness.

Ebner-Eschenbach, a master of realistic prose, was the author of the short-story collections *Stories of Life in the Village and the Castle* (1883) and *New Stories of Life in the Village and the Castle* (1886). Satirizing the Austrian bourgeoisie and aristocracy, she sympathized with the common people, who were deprived of rights. The moral superiority of simple people is asserted in her novels *Božena* (1876) and *Lotti the Watchmaker* (1889). Ebner-Eschenbach's works are somewhat flawed by a moralizing tone and sentimentality.

EBOLOWA, a city in Cameroon, located in the South Central Province. Population, 24,000 (1970). Ebolowa is linked by highway with the city of Yaoundé and the port of Douala. It is a trade and transportation center of a region specializing in the cultivation of cacao and lumbering. [29–1631–3]

EBONITE, a product resulting from the vulcanization of rubber with large quantities of sulfur, about 30 to 50 percent per mass of rubber. Ebonites are hard materials and, unlike "soft" rubbers, display no high-elastic properties at ordinary temperatures. They lend themselves readily to mechanical processing, are nonhygroscopic and impermeable to gas, and are resistant to the action of solutions of acids, bases, salts, plant oils, and animal fats. They are decomposed by strong oxidizing agents and by aromatic and

chlorinated hydrocarbons. Ebonites have a density of 1.15–1.68 g/cm^3, a Young's modulus of 2–3 giganewtons/m^2 (20×10^3 to 30×10^3 kilograms-force/cm^2), a tensile strength of 52–67 meganewtons/m^2 (520–670 kilograms-force/cm^2), and a volumetric resistivity of 1–10 teraohm·m (10^{14}–10^{15} ohm· cm).

Ebonites are used to manufacture electric insulating components of devices and to rubberize various vessels used for corrosive liquids. In many areas of technology, ebonites are being replaced by plastics, which have superior dielectric properties and chemical stability.

Entsiklopediia polimerov, vol. 3. Moscow, 1977. [29–1631–4]

EBONY, the dark wood of several species of tropical trees of the family Ebenaceae and several other families (Mimosaceae, Papilionaceae). Its color ranges from green to black. The best grades of ebony come from the tropical *Diospyros crassiflora, D. ebenum, D. haplostylis, D. melanoxylon*, and *D. reticulata*. The black heartwood is uniform in structure, heavy (with a density greater than 1), and hard. The annual rings and medullary rays are unnoticeable. Green ebony is obtained chiefly from the Central American *Tecoma leucoxylon* of the family Bignoniaceae.

Ebony is used as an ornamental facing for expensive furniture. It is also used in inlaid work and for the manufacture of musical instruments and various other wooden articles. The wood of *D. lotus*, from Transcaucasia and Middle Asia, is used in the USSR as an ebony substitute. It is used for various lathed objects, in joinery, and in the manufacture of shuttles for looms. [29–1628–3]

EBRO, a river in northeastern Spain. The Ebro measures 928 km in length and drains an area of 86,800 sq km. It originates on the southern slopes of the Cantabrian Mountains and in a deep valley intersects the northeastern part of the Old Castile Plateau; in its middle course it intersects the Aragon Plain, where it divides in places into channels. In its lower course, along narrow, meandering gorges, it bursts through the spurs of the Catalonian Mountains, below which it reaches the maritime plain. It flows into the Mediterranean Sea, forming a delta (approximate area, 250 sq km), within which it flows in a straightened, embanked channel.

The water level increases in winter and spring, sometimes by as much as 4–6 m during floods. In summer and autumn the flow rate decreases, although flash floods occur. The mean flow rate in the lower course is 560 cu m per sec, with a maximum of 8,000 cu m per sec.

Within the Aragon Plain the Aragon and Tauste irrigation canals extend from the Ebro, watering more than 100,000 hectares (ha) of the Ebro valley. Hydroelectric power plants are found on the river. The Ebro is navigable below the city of Zaragoza. Other cities situated on the river include Miranda de Ebro, Logroño, and Tortosa. [29–1631–5]

EBULLIOSCOPY (also ebulliometry), a method of physicochemical analysis based on measuring the increase in the boiling point of a solution in comparison with the boiling point of a pure solvent.

According to Raoult's laws (*see* RAOULT'S LAWS), for an infinitely diluted solution of a nonvolatile substance and in the absence of electrolytic dissociation, this increase, Δt_b, is proportional to the molal concentration m of the solution; $\Delta t_b = E_e m$, where E_e is the coefficient of proportionality (ebullioscopic constant), which is characteristic of each solvent and does not depend on the nature of the solute. Thus, E_e for water is equal to 0.526; for benzene, 2.57; for dioxane, 3.27; for camphor, 6.02; and for dibromoethane, 6.43; all quantities are expressed in °C. Along with cryoscopy, ebullioscopy is used to determine the molecular mass of a solute, the activity of the solvent and the solute, or the degree of dissociation of the weak electrolyte. The molecular mass M of the solute is computed according to the equation

$$M = \frac{P_1 E_e \times 1{,}000}{P_2 \Delta t_b}$$

where P_1 and P_2 are the masses of the solute and the solvent, respectively, expressed in grams. The temperature difference Δt_b is measured by means of a Beckmann thermometer or sensitive thermocouples.

ECCARIUS, JOHANN GEORG. Born Aug. 23, 1818, in Friedrichroda; died March 1899 in London. Figure in the German and international working-class movement.

A tailor by profession, Eccarius was a member of the League of the Just and, later, of the Communist League; when the Communist League split in 1850, he sided with K. Marx. In London he was a leader of the German Workers' Educational Society. Eccarius helped found and took part in the First International; he served as a member of the General Council from 1864 to 1872, as general secretary from 1867 to 1871, and as corresponding secretary for America from 1870 to 1872. After the London Congress of the International in 1871 he aligned himself with reformist trade union leaders, and he supported the bourgeois and reformist elements in the International. After the First International ceased its activities, Eccarius took part in the trade union movement. [29–1765–5]

ECCLES, JOHN CAREW. Born Jan. 27, 1903, in Melbourne. Australian physiologist.

Eccles graduated from the University of Melbourne in 1925 and from Magdalen College, Oxford, in 1929. He worked in Oxford from 1927 to 1937 under C. Sherrington and was director of the Kanematsu Memorial Institute of Pathology in Sydney from 1937 to 1944. He was professor of physiology at Otago University, New Zealand, from 1944 to 1951 and professor of physiology at the Australian National University in Canberra from 1951 to 1966.

Eccles served as president of the Australian Academy of Sciences from 1957 to 1961. He worked in the Institute for Biomedical Research in Chicago from 1966 to 1968 and became a distinguished professor and director of the Institute of Neurobiology and dean of the department of public health of the State University of New York at Buffalo in 1963.

Eccles has mainly done research on electrical processes in nerve cells. He made an important contribution to the study of the ionic mechanisms of excitation and inhibition of nerve cells. He showed how nerve impulses arise in one cell and are then transmitted to an adjacent cell. Eccles has been a fellow of the Royal Society since 1941. He was awarded a Nobel Prize in 1963, along with A. L. Hodgkin and A. F. Huxley.

ECCLESIA, the most common name for the popular assembly in ancient Greece. In the Athens of Pericles (mid-fifth century B.C.) and in other democratic poleis, or city-states, the ecclesia was the highest governmental body. It elected officials and exercised legislative, executive, and judicial power. In oligarchic poleis the authority of the ecclesia was limited by other governmental bodies, such as councils and collegia.

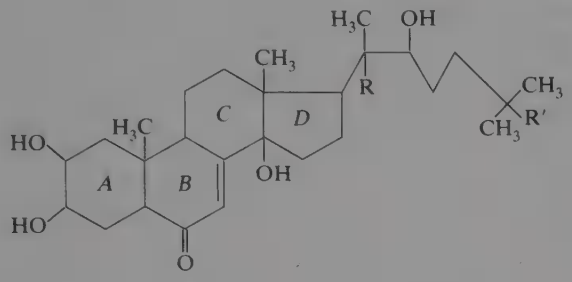
In many poleis, the popular assembly was given a special name; the term *apella* was used in Sparta, the term *agora* in Delphi and the cities of Thessaly, and the term *alia* in Argos, Epidaurus, Gela, and Acragas (present-day Agrigento). Writers of late antiquity used the word "ecclesia" to refer to the place where a popular assembly was held.

In Christian writings, "ecclesia" may mean either the community of believers or the church as a whole. [29–1766–2]

ECDYSONE, any of the group of steroid hormones that stimulate molting and metamorphosis in arthropods. Some varieties—especially α-ecdysone and ecdysterone, either separately or to-

gether—function as molting hormones in different groups of arthropods.

In 1954, A. Butenandt isolated α-ecdysone from silkworm cocoons; in 1965 the chemical structure of the hormone was determined by chemical methods and by X-ray diffraction analysis. α-Ecdysone has the structural formula



where R = H and R′ = OH. (In ecdysterone, R = R′ = OH, and in ponasterone, R = OH and R′ = H.) Ecdysones are solid, optically active substances that are slightly soluble in water but readily soluble in polar organic solvents. They contain 27 or 28 carbon atoms. Four structural features are characteristic of most ecdysones: the cis linkage of rings *A* and *B*, the *cis*-glycol group in ring *A*, the α- and β-unsaturated ketone groups in ring *B*, and at least one hydroxyl group (usually two or three) in the sterol side chain.

Ecdysones are formed by the thoracic gland in insects and by the Y organ in crustaceans; the activity of the organ increases at the time the shell is shed. Ecdysones cause the epidermis to release the molting secretion that causes the formation and hardening of a new cuticula. Ecdysones also initiate pupal molting, which is accompanied by the transformation of the larvae into pupae and by the formation of a special melting cocoon (puparium). For this reason, ecdysones are used by sericulturists in Japan to hasten the formation of silkworm cocoons and facilitate manual sorting. At present, the use of ecdysones as insecticides that work by hormonal action does not appear promising.

Ecdysones act on insects by inducing chromosome puffs (zones of genetic activity). Successively arising puffs sequentially activate genes involved in the transmission of genetic information. In this manner ecdysones activate, for example, dioxyphenylalanine decarboxylase, an enzyme needed to synthesize the substances responsible for sclerotization of the insects' cuticula. Ecdysones induce the formation of protein by stimulating the biosynthesis of messenger ribonucleic acids (mRNA). The balanced action of ecdysones, combined with that of the juvenile hormones, regulates the stages of insect development.

The concentration of ecdysones in arthropods is very low, ranging from 0.1 microgram per gram (μg/g) to 1.0μg/g. Certain ecdysones, including amarosterone and cyasterone, are also found in plants in concentrations ranging from 0.1 percent to 1–2 percent, but their physiological function is still unknown. Plant ecdysones contain 27, 28, or 29 carbon atoms. The assumption that the hormones protect plants against herbivorous insects has not been experimentally proved. It is worth noting that ecdysones stimulate the growth of such plants as peas and rice and that the plant hormone gibberellin induces molting in the locust.

EÇEVIT, BÜLENT. Born May 28, 1925, in Istanbul. Turkish state and political figure; a literary critic and theorist by education.

Eçevit graduated from Robert College in Istanbul in 1944. Between 1946 and 1950 he was on the staff of the Turkish press attaché in London. From 1950 to 1961 he was employed in various capacities by the newspaper *Ulus*, an organ of the Republican People's Party (RPP).

Eçevit became an RPP member of the Grand National Assembly in 1957. Between 1961 and 1965 he served as minister of labor in the coalition governments led by I. Inönü. He was secretary general of the RPP from 1966 to 1971 and general chairman of the party from May 1972 to October 1980. Eçevit served as prime minister from January to November 1974 and again from January 1978 to November 1979. [29–1681–4]

ECKERMANN, JOHANN PETER. Born Sept. 21, 1792, in Winsen, Bavaria; died Dec. 3, 1854, in Weimar. German literary figure. Secretary and friend of Goethe.

From 1821 to 1823, Eckermann studied literature and aesthetics at the University of Göttingen. His *Conversations With Goethe in the Last Years of His Life* (parts 1–3, 1837–48; first abridged Russian translation, 1891; complete translation, 1934) is more complete and of higher literary quality than any other memoir about the poet. Eckermann put Goethe's archives into order and prepared his works for publication. He was also the author of lyric poems, which were published in collections in 1821 and 1838.

ECKERSBERG, CRISTOFFER VILHELM. Born Jan. 2, 1783, in Blaakrog; died July 22, 1853, in Copenhagen. Danish painter.

Eckersberg began his art studies at a school affiliated with the Academy of Arts in Copenhagen, and from 1810 to 1813 he studied in J. L. David's studio in Paris. He lived in Rome from 1813 to 1816. He was a Professor at the Academy of Arts in Copenhagen from 1818 and served as its director from 1827 to 1829.

The works of Eckersberg, strongly influenced by classicism, had an important influence on the development of the national Danish school of painting. They include expressive portraits executed in a severe style, for example, *Portrait of Thorwaldsen* (1814, Charlottenborg, Copenhagen), and landscapes noted for their delicate and light palette. [29–1766–1]

ECK'S FISTULA, an experimental method of partly interfering with liver function. The operation was proposed in 1877 by the Russian surgeon N. V. Eck (Ekk) and was successfully used in 1892 by I. P. Pavlov. It involves the surgical connection of the vena cava inferior to the portal vein, which is simultaneously ligated above the point of connection. As a result, the blood bypasses the liver, flowing directly into the vena cava inferior. Eck's fistula is a classical method of studying liver function. Various ways of improving and simplifying it have been suggested. [29–1765–4]

ECLAMPSIA, a serious disease occurring during pregnancy, labor, or the postpartum period. Eclampsia is a late stage of toxemia of pregnancy. The condition is characterized by convulsions that develop in a definite sequence. Slight fibrillar contractions of the facial muscles (15–30 seconds) are followed by tonic spasms of the total skeletal musculature and loss of consciousness (15–20 seconds). Clonic muscular spasms of the trunk and limbs occur, and, finally, the woman lapses into a brief or prolonged coma. Consciousness returns gradually. In particularly severe cases, eclampsia may occur without convulsions (comatous forms). Eclampsia is often manifested by only a few convulsions, and high blood pressure may not be a symptom. Death may occur during or after convulsions as a result of pulmonary edema, hemorrhages into the brain, and asphyxia. The fetus often dies *in utero* from hypoxia. The prognosis depends on the number and duration of the convulsions or on the duration of the coma.

Current treatment of eclampsia is based on principles developed by the Soviet obstetrician-gynecologist V. V. Stroganov in 1928. Total physical and mental rest is prescribed. Functioning of the vital organs is restored: Drugs are administered to decrease

the excitability of the central nervous system, to lower blood pressure, and to stimulate urination. Oxygen is administered in cases of pronounced hypoxia, and labor is induced quickly but cautiously. The patient should not be moved during convulsions or while in a coma. Prompt hospitalization is required as soon as consciousness is regained. Prophylaxis includes the prevention of advanced toxemia and prompt hospital treatment of neuropathy and preeclampsia.

ECLECTICISM, in art and architecture, the combination of artistic elements of diverse origin; the phenomenon usually occurs during the period of decline of major artistic trends.

Elements of eclecticism are noticeable in late ancient Roman art, mainly in the combination of forms borrowed from Greece, Egypt, and Southwest Asia. The artists of the Bolognese school favored eclecticism, believing that they could attain artistic perfection by combining what in their opinion were the best aspects of works by the great masters of the Renaissance.

Eclecticism is characteristic of the architecture, especially the interior design, of the middle and second half of the 19th century, when different motifs were mixed indiscriminately, including those of the Renaissance and rococo styles; however, the eclecticism typical of 19th-century architecture and design, with their universal range of architectural and ornamental motifs, had a significant impact on the birth of *art nouveau*, which was essentially a distinct, integral style although influenced by the most diverse sources.

Eclecticism has remained typical of salon art. Eclectic trends became widely popular in Western European and American artistic culture of the mid-20th century as a result of the vogue for retrospective styles of artistic design, which copy stylistic trends of the past.

ECLECTICISM, the combination of diverse views, ideas, and theories. The term was introduced in the second century by Potamon of Alexandria, who called his school eclectic. The sources of eclecticism lie in the substitution of one set of logical foundations for another. The shallowness and futility of such constructions have been noted by many philosophers, beginning with Socrates and Aristotle. The classics of Marxism-Leninism were sharply critical of eclecticism. V. I. Lenin pointed out the substitution of foundations—the undermining of the integrity of an object—that is a characteristic feature of eclecticism: "the substitution of eclecticism for dialectics is the easiest way of deceiving the people. It gives an illusory satisfaction; it seems to take into account all sides of the process, all trends of development, all the conflicting influences, and so forth, whereas in reality it provides no integral and revolutionary conception of the process of social development at all" (*Poln. sobr. soch.*, 5th ed., vol. 33, p. 21).
[29–1767–2]

ECLIPTIC, the great circle on the celestial sphere along which occurs the apparent annual motion of the sun or—more precisely—the apparent annual motion of the center of the sun. Since the apparent annual motion of the sun reflects the actual motion of the earth about the sun, the ecliptic may be regarded as the intersection of the celestial sphere and the plane of the earth's orbit.

The plane of the ecliptic is inclined to the plane of the celestial equator by an angle of $\epsilon = 23° 27' 8''.26 - 0.4685t$, where t is the number of years that have elapsed since the beginning of 1900. The equation is valid for several centuries after the 20th century. The angle of inclination, which is called the obliquity of the ecliptic, varies periodically over hundreds of thousands of years.

The term "ecliptic" is associated with the fact, known since ancient times, that solar and lunar eclipses occur only when the moon is near one of the points where its orbit intersects the ecliptic. These points on the celestial sphere are called the lunar nodes. The ecliptic passes through 12 constellations, which are known as the zodiacal constellations. The plane of the ecliptic is the fundamental plane in the ecliptic system of celestial coordinates. [29–1768–2]

ECLOGA, a brief code of Byzantine law, promulgated by Emperor Leo III the Isaurian in the year 726. The Ecloga was a revision of parts of the codification of Justinian, the Rural Code, and other acts promulgated by Byzantine emperors. It was drawn up in order to make the legislation less cumbersome and more comprehensible to the people of Byzantium. It dealt mainly with liability, the family, inheritance, and norms of criminal and procedural law. Although it provided for slavery as before, it reflected a more advanced stage of feudal relations; in particular, the procedure for liberating slaves was simplified. The Ecloga influenced several legislative works of the Slavic peoples. [29–1769–3]

ECLOGITE, a metamorphic rock, composed chiefly of clinopyroxene and garnet. The clinopyroxene (omphacite) is a mixture of diopside, hedenbergite, and jadeite components; the mixed-composition garnet contains pyrope and almandine, as well as variable amounts of grossularite and andradite. Eclogite varieties with significant amounts of grossularite and disthene (kyanite) are called grospydites.

Various types of eclogite are distinguished according to the content of secondary minerals, including amphibole, enstatite, olivine; plagioclase, kyanite (disthene), corundum, rutile, graphite, and diamond-containing eclogites. Three types are distinguished on the basis of geological conditions of occurrence: the eclogites of the metamorphic zone, which are associated with glaucophane schists and alpine-type hyperbasites; the eclogites of granulite, gneiss, and amphibolite metamorphic complexes; and eclogites that form inclusions (xenoliths) in kimberlites and alkali basaltoids. The first two are formed within the crust; the last is of mantle origin. Deposits of rutile are associated with eclogite, and diamonds are found among the most deep-seated eclogites in kimberlite pipes. A. A. MARAKUSHEV [29–1769–4]

ECLOGITE FACIES, conditions of thermodynamic stability of eclogites, defined with respect to the principal factors of metamorphism: pressure, temperature, and partial pressures of volatile components in fluids. Eclogites correspond to conditions of high pressure attained in the earth's crust (almandine eclogites, 7–15 kbar) or in the mantle (pyrope eclogites, more than 15 kbar).

In terms of temperature, a distinction is made between medium-temperature eclogites, which are part of alpine-type glaucophane metamorphic zones (500°–600°C), and high-temperature eclogites, which form associations with gneisses and granulites (600°–900°C). The pyrope eclogites that form inclusions in kimberlites and alkali basaltoids have even higher temperatures (above 900°C).

A number of scientists, such as A. A. Marakushev and L. L. Perchuk, believe that the metamorphism leading to the formation of eclogites originates under reduction conditions with the participation of fluids with low partial pressures of water and carbon dioxide. Under such conditions, the processes of hydration and carbonatization of minerals are relatively suppressed, which gives anhydrous minerals (omphacite, garnet) stability in both high- and medium-temperature facies.

A. A. MARAKUSHEV [29–1769–5]

ECLOGUE, a type of idyll. An eclogue is a genre scene, usually a love scene, of conventional pastoral life. It may be written in narrative or dramatic form. In classical literature no distinction was made between the idyll, for example, those of Theocritus, and the eclogue, for example, Vergil's *Bucolics*. Writers of the 18th-century classical school considered that the idyll required more emotion, and the eclogue more action; such were the first Russian eclogues, by A. P. Sumarokov. However, the distinction was not strictly observed. The genre had become obsolete by the early 19th century. [29–1769–2]

ECNOMUS, the ancient Roman name for the promontory now called Poggio Sant'Angelo, which is located on the southern coast of Sicily at the mouth of the Himera Meridionalis (now Salso River), near modern Licata.

In 256 B.C., during the First Punic War (264–241 B.C.), a naval battle between the Roman and Carthaginian fleets took place near Ecnomus. The Roman fleet, comprising 330 ships under the command of the consul M. Atilius Regulus, was escorting transports of landing forces headed for North Africa. Two detachments of ships sailed ahead, and two formed a protective line behind the transports. Near Ecnomus the Roman fleet was met by the Carthaginians, whose fleet comprised 350 ships under the command of Hamilcar.

The advance Roman detachments attacked. Hoping to divert the advance Roman detachments, Hamilcar ordered his two central detachments to withdraw; the two flank detachments were ordered to sail toward the transports and destroy them. The advance Roman detachments, however, defeated the enemy's central detachments, which were forced to flee; they then returned to aid the rear detachments, which had waged a stubborn battle with the Carthaginians' flank detachments, and proceeded to rout the enemy. Of the Cathaginian ships, 30 were sunk and 64 captured. The Romans lost 24 ships. The victory at Ecnomus made it possible for the Romans to land safely in North Africa.

[29–1770–4]

ECOBIOMORPH, a certain type of adaptive structure, including related physiological features, characterizing a group of plants that usually are not related but that inhabit similar environments. The term was proposed by E. M. Lavrenko in 1965 to replace the term "life form," or "biomorph." It differs from the latter two in that it takes into account physiological as well as morphological features. [29–1771–1]

ECOGENESIS, the development in the course of evolution of ecological relations between organisms and their environment. The term "ecogenesis" was introduced in 1904 by the German scientist K. Detto, who used it to denote the process of adaptation in general. Ecogenesis is sometimes defined as the process whereby new forms appear under the influence of the environment. Ecogenesis, or ecogenetic succession, is also used for floral succession, the main cause of which is a change in ecological conditions engendered by the plants themselves (endogenous succession) or by external factors (hologenetic succession). [29–1771–2]

ECOLOGICAL AMPLITUDE (also ecological valence), the degree of adaptation of a living organism to changes in its environment. A species trait, ecological amplitude is expressed quantitatively as the range of environmental changes within which a given species is able to carry on its normal vital activities.

Ecological amplitude can be examined as either the reaction of a species to individual environmental factors or to an aggregate of factors. In the first case, species that are able to tolerate a wide range of changes in the strength of an acting factor are designated by a term consisting of the name of the given factor and the prefix "eury," such as eurythermal (referring to the effects of temperature), euryhaline (salinity), and eurybathic (depth). Species that are adapted to only a narrow range of changes in a given factor are designated by the same term with the prefix "steno," for example, stenothermal and stenohaline. Species that exhibit broad ecological amplitude with respect to an aggregate of factors are called eurybionts, while species with low adaptability are called stenobionts. Inasmuch as euroky makes it possible for a species to occupy a variety of habitats while stenoky sharply curtails the range of suitable habitats, these two groups are often referred to as eurytopic and stenotopic, respectively.

I. A. SHILOV [29–1771–3]

ECOLOGICAL NICHE, the role of a species (more precisely, its population) in a biological community (biocenosis). The interaction of a given species (population) with other members of the community establishes its role in the cycle of matter, determined by food and competition ties in the biocenosis.

The term "ecological niche" was proposed by the American scientist J. Grinnell (1917). The interpretation of the ecological niche as the position of a species in the food chain of one or several biocenoses was proposed by the British ecologist C. Elton (1927). Such an interpretation makes it possible to assign a quantitative value to the ecological niche of each species or its individual populations. In order to accomplish this, a comparison is made, within a system of coordinates, between the abundance of a species (the number of individuals or the biomass) and an indicator of the temperature, humidity, or some other environmental factor. In this way, it is possible to establish the optimum zone and the limits tolerated by a species (the maximum and minimum for each factor or combination of factors).

As a rule, every species occupies a specific ecological niche, to which it has become adapted by the entire course of evolutionary development. The location that a species (population) occupies in space (spatial niche) is usually called the habitat.

N. P. NAUMOV [29–1772–1]

ECOLOGY, a biological science that studies the organization and functioning of supraorganismic systems at various levels: populations, species, biocenoses (communities), ecosystems, biogeocenoses, and the biosphere. Ecology is also often defined as the science of the interrelations of organisms and the science of the relations between organisms and their environment. Modern ecology also studies man's interaction with the biosphere.

Main subdivisions. Ecology is subdivided into general ecology, which investigates the fundamental principles of the organization and functioning of various supraorganismic systems, and specialized ecology, which is restricted to the study of concrete groups of a given taxonomic rank.

General ecology is classified according to the organizational levels of the supraorganismic systems. Population ecology (*see* POPULATION ECOLOGY) studies populations—assemblages of individuals of a particular species united by a common territory and gene pool (*see* GENE POOL). Community ecology (or biocenology) studies the structure and dynamics of natural communities (or cenoses), which are assemblages of populations of different species living together (*see* POPULATION). Biogeocenology is a subdivision of general ecology that studies ecosystems (biogeocenoses). (*See* BIOGEOCENOLOGY; ECOSYSTEM; and BIOGEOCENOSIS.) In the USSR and some European countries, biogeocenology is sometimes treated as an independent science, separate from ecology. In the USA, Great Britain, and many other countries, the term "ecosystem" is more commonly used than "biogeocenosis," and biogeocenology is not differentiated as a separate science.

Specialized ecology comprises plant ecology and animal ecology. Microbial ecology and the ecology of fungi have emerged relatively recently. A more detailed subdivision of specialized ecology is also proper, such as the ecology of vertebrates, the ecology of mammals, and the ecology of the blue hare.

There is no consensus among scientists with respect to the principles according to which ecology should be subdivided into general and specialized ecology. According to some, the main object of study of ecology is the ecosystem, while the subject of specialized ecology reflects the subdivision of ecosystems, for example, terrestrial and aquatic ecosystems; aquatic ecosystems are subdivided into marine and freshwater ecosystems, freshwater ecosystems are, in turn, subdivided into the ecosystems of rivers, lakes, reservoirs, and so on. Hydrobiology studies the ecology of aquatic organisms and the systems that they form (*see* HYDROBIOLOGY).

Ecology is often also subdivided into autecology, which studies the relationship of individual species to the environment, chiefly abiotic factors, and synecology, which studies communities and biogeocenoses; this subdivision was proposed by the Swiss botanist Schröter (*see* AUTECOLOGY and SYNECOLOGY). The two are linked by population ecology.

There is no consensus in the world literature regarding the definition of plant ecology. In the USSR and European countries, with the exception of Great Britain, plant ecology is limited to autecology, and the study of plant communities is relegated to phytocoenology or geobotany (*see* PHYTOCOENOLOGY). In the USA and Great Britain, plant ecology studies both individual species and communities.

Many branches of ecology have a manifestly practical purpose, for example, agricultural ecology, which studies agricultural ecosystems created by man (*see* AGROPHYTINOENOSIS).

The effect of the environment on human society and the features of urbanized biogeocenoses are the subject of human ecology, which emerged in the mid-20th century. The increased danger of the radioactive contamination of the environment gave rise to radioecology (*see* RADIOECOLOGY). The study of the biosphere, which as yet has no name, is being developed in close association with biogeochemistry (*see* BIOGEOCHEMISTRY). The relations between organisms and the abiotic and biotic environment in past geological epochs and the problems of reconstructing ancient biocenoses from buried remains is the subject of paleoecology (*see* PALEOECOLOGY).

History. The term *oekologie* was proposed in 1866 by the German zoologist E. Haeckel, who defined ecology as the general science of the relations of organisms to their environment, to which are relegated, in the broad sense, all "conditions of existence."

The history of ecology can be traced back to the works of ancient Greek and Roman natural philosophers. Valuable ecological observations are found in the works of 18th-century naturalists, especially C. Linnaeus, G. de Buffon, P. S. Pallas, and I. I. Lepekhin. The concept of ecology originated in the sciences of botany and zoology. Its development was influenced, first and foremost, by works that studied the mode of life of organisms and the distribution and development of organisms as a function of various environmental factors. The importance of research on the geographical distribution of plants was especially significant, since it was ecological by nature from the outset.

In the early 19th century, the German naturalist A. von Humboldt, on the basis of long-term observations in Central and South America, showed the dependence of altitudinal and latitudinal zonality on temperature and gave the first classification of the life forms of plants (*see* LIFE FORM). The Swiss botanist A. P. de Candolle even distinguished the science of "epirrheology" (1832) for the study of the interrelations of plants and the environment.

The work of K. F. Rul'e was important in the development of ecology in Russia. Rul'e emphasized the necessity of studying animals in relation to other organisms and to the abiotic environment and gave special consideration to the role of conditions created by man (the anthropogenic factor). N. A. Severtsov's *Periodic Phenomena in the Life of Animals, Birds, and Reptiles of Voronezh Province* (1855) was a true ecological study, analyzing extensive material on seasonal phenomena in the life of terrestrial vertebrates of Voronezh Province.

By the mid-19th century, many successes were achieved in agricultural chemistry. According to the law of the minimum, formulated by the German scientist J. von Liebig, under actual conditions not all nutrient substances limit a harvest but only those that are present in quantities that are inadequate for the plant. With certain refinements, this principle later became one of the most important ones in examining the factors that limit the reproduction or growth of organisms.

C. Darwin's *The Origin of Species* (1859) was instrumental in the establishment of ecology as an independent science. It emphasized the importance of studying the mechanisms of the struggle for survival and of intraspecific and interspecific relations. Under the direct influence of Darwin's idea, Haeckel concluded that ecology must be established as a separate biological discipline. An important stage in the development of ecology was the acceptance of the need for a holistic approach to the study of natural plant and animal communities, which was facilitated by the introduction of special terms for describing such communities. The term "biocenosis," proposed by the German zoologist K. Möbius in 1877, quickly spread throughout the European, including Russian, scientific literature. The term "community" is more commonly used by American scientists.

At the beginning of the 20th century, the complex problem was posed of studying the assemblage of plants and animals in their relation to the abiotic environment. To this end, much success was achieved in the study of inland bodies of water, which can more easily be viewed as integral systems and described by means of generalized indicators (the Swiss scientist F. Forel and the German researcher C. Knauth). The study of various forms of life in an aquatic environment came to be called hydrobiology. Hydrobiologists were the first to study the role of organisms in the cycle of matter and the transformation of energy in nature (the American scientists E. Birge and C. Juday). They formulated concepts that proved important for the development of ecology in general, such as biomass (the German scientist R. Demoll) and productivity (the German scientist A. Thienemann). (*See* BIOMASS.)

The quantitative study of the cycle of matter on land began in the 1930's, 1940's, and 1950's. Necessary prerequisites for this were the advances in soil science, which originated in Russia; of particular importance was V. V. Dokuchaev's introduction, at the end of the 19th century, of the idea of the soil as a special body in natural history, created by the interaction of the abiotic and biotic components of the environment. V. I. Vernadskii described such natural bodies as biologically integral.

Much of the ecological research on land in the late 19th and early 20th centuries was carried out independently by botanists and zoologists, reflected in the publication of the first ecological summaries: on plant ecology (more precisely, ecological geography) by the Danish botanist J. Warming (1895) and the German scientist A. Schimper (1898) and on animal ecology by the German zoologist R. Hesse (1912) and the American scientist C. Adams (1913). At the beginning of the 20th century, attention was focused on plant communities. Phytosociology (later called phytocoenology), which studies the organizational regularities of plant communities (I. K. Pachoskii, S. N. Korzhinskii, P. N. Krylov), emerged in Russia (*see* PHYTOCOENOLOGY). The regularities of the process of community replacement—succession (*see* SUCCESSION)—were also studied intensively (the Finnish scientist R. Hult and the American scientist H. Cowles). The American botanist F. Clements, who studied succession, attempted to draw analogies between the structure and development of the organism and the community. Among the milestones in the study of plant communities were G. F. Morozov's *A Study of the Forest* (1912) and V. N. Sukachev's *Introduction to the Study of Plant Communities* (1915). Prominent scientific schools of phytocoenology developed in Western Europe, including the Franco-Swiss school, first in Zürich (C. Schröter, E. Rübel, H. Brockman-Jerosch) and then in Montpellier (J. Braun-Blanquet), and the Scandinavian school in Uppsala (G. Du Rietz).

Animal ecologists also became increasingly interested in the study of communities. Consequently, the American scientist V. Shelford, who contributed much to various areas of ecology, defined ecology as the science of communities, relegating autecology entirely to physiology. Theoretical ecology was greatly influenced by C. Elton's *Animal Ecology* (1927), in which the problem of studying the organization (structure) of communities was formulated, the regularities of the relations between the numbers of organisms at different trophic levels (pyramid of numbers) were described, the concept of the ecological niche, proposed earlier by the American zoologist J. Grinnell (1917), was clarified, and attention was focused on variations in the size of populations. The experimental study of populations was begun in animal ecology. The American scientist R. Chapman introduced the concept of biotic potential, which characterizes the rate of growth (reproduction and survival) of a population. The Australian entomologist A. Nicholson (1933) described population dynamics as a self-regulating process. By the 1930's, a population came to be understood in animal ecology as an integral assemblage of individuals that was endowed with certain characteristics and that could not be reduced to the simple sum of its parts.

In the 1920's and 1930's, the methods of mathematical statistics (including those used earlier in demography) and modeling began to be used in ecology. The Italian researcher V. Volterra (1926) and the American scientist A. Lotka (1925) developed mathematical models of the growth of individual populations and

of the dynamics of populations interrelated by competition and predation.

In the years after the Great October Socialist Revolution, Soviet ecologists began an intensive study of the plants and animals in various topographical and geographical zones of the USSR. L. G. Ramenskii developed the concept of the continuum of the plant cover (*see* CONTINUUM OF VEGETATION) and introduced the concept of the ecological individuality of a species and the concept of consortium (*see* CONSORTIUM).

The Soviet scientist V. I. Vernadskii established the study of the biosphere in the 1920's and 1930's (*see* BIOSPHERE). His ideas greatly influenced ecological thought in the USSR and abroad, generating particular interest in the 1950's and 1960's, in great measure in connection with the increased threat of global disruption of the biosphere as a result of man's activities.

The experimental work of Soviet scientist G. F. Gauze (Gause) on protozoans and microorganisms became internationally known. Gauze formulated the principle of competitive exclusion, according to which two species occupying the same ecological niche cannot exist in the same place for an unlimited period of time.

Of great importance in the USSR in the dissemination of ecological ideas and the training of ecological researchers were D. N. Kashkarov's compendiums *The Environment and the Community* (1933) and *The Fundamentals of Animal Ecology* (1938). As ecology developed, its content and definition gradually changed. Thus, in the 1930's ecology emphasized the study of the adaptation of organisms to their environment. The study of communities of organisms was sometimes considered to be the subject of an independent science—biocenology. Using extensive material on the population dynamics of vertebrates, S. A. Severtsov tied in (1941) new sociological ideas with concepts of the theory of evolution, defining ecology as the science of the mechanisms of the struggle for survival.

Soviet plant ecologists are continuing the experimental course set by V. N. Sukachev in phytocoenology, whose main task is the study of the mechanisms of intraspecific and interspecific competition.

In the 1930's, 1940's, and 1950's, animal ecologists in the USSR conducted field studies: they analyzed fluctuations in the numbers of harmful rodents and game mammals (B. S. Vinogradov, N. P. Naumov, O. I. Semenov-Tian-Shanskii, S. P. Naumov, A. N. Formozov), studied the effects of snow cover on animals (A. N. Formozov, A. A. Nasimovich, V. P. Teplov), and investigated soil invertebrates (M. S. Giliarov).

The extensive use of quantitative methods also became characteristic of marine hydrobiology (S. A. Zernov, I. I. Mesiatsev, A. A. Shorygin, V. G. Bogorov, V. P. Vorob'ev), in whose development the scientific, organizational, and pedagogical activities of L. A. Zenkevich played an important part. A new direction emerged in hydrobiology, involving the study of the biological productivity of bodies of water (*see* BIOLOGICAL PRODUCTIVITY). Important work was carried out in this area by Soviet scientists, particularly at the Kosino Limnological Station near Moscow by L. L. Rossolimo, E. V. Borutskii, S. N. Kuznetsov, G. S. Korzinkin, and others. The primary production of a body of water was first determined there from the rate of photosynthesis (G. G. Vinberg, 1932).

The formulation of the concept of ecosystem and the concept of biogeocenosis was of great significance for the development of ecology. The English botanist A. Tansley defined (1935) an ecosystem as any assemblage of organisms living together (autotrophs and heterotrophs), along with the abiotic environment necessary for their existence. The more specific concept of a biogeocenosis, as established by V. N. Sukachev, presupposes the unity of the plants, animals, and microorganisms that inhabit a particular section of the earth's surface, taking into account its terrain, climate, soil, and hydrological conditions. The introduction of these concepts helped bring together the different divisions of ecology and made it possible to pose such general problems in ecology as the study of the cycle of matter and energy flow in an ecosystem. The concept of trophic (feeding) levels made it possible to describe quantitatively the process of the conversion of matter and energy upon moving from one level to another (the American ecologists G. E. Hutchinson, R. Lindeman, and H. Odum). The Soviet scientist V. S. Ivlev, who investigated the energy and production aspects of trophic levels, is also known for his research into the quantitative characteristics of fish nutrition.

In the 1940's and 1950's the Soviet botanist T. A. Rabotnov, and in the 1960's A. A. Uranov, developed the study of plant populations. Similar work was later carried out abroad (the British scientist J. Harper).

Along with the increased study of populations and ecosystems, autecology also developed in the USSR. Autecology is closely related to physiology and makes extensive use of experimental methods (I. D. Strel'nikov, I. V. Kozhanchikov, V. V. Alpatov, N. I. Kalabukhov, A. D. Slonim). The Soviet scientist A. S. Danilevskii made important contributions to the study of photoperiodism in animals. In general, ecology in the USSR is characterized by practically oriented research, with emphasis on the solution of national economic problems. Ecological trends in parasitology (V. A. Dogel', K. I. Skriabin, V. N. Beklemishev) led to the new study of the natural sources of human diseases and diseases of domestic animals (E. N. Pavlovskii and others).

General ecology was established in the 1950's. Its development was predicated on the following: the achievements of hydrobiology, primarily the energy and production aspects; the interpretation of much factual material gathered on the ecology of terrestrial animals and on plant ecology; the formulation of the concepts of ecosystem and biogeocenosis; and the wide application of mathematical methods, a systematic approach, and conceptions about the levels of organization of living matter. In the first compendiums on general ecology (the American ecologists G. Clarke and E. Odum), much attention was devoted to ecosystems. General ecology also studies the basic principles of the organization of populations and communities.

A rapid growth in ecological research was observed throughout the world in the 1960's and 1970's. Among the reasons for this are the acceptance of ecology as a science, the precise definition of the objects and methods of study, and the pressing need to improve the productivity of ecosystems and protect the environment, a need that has increased dramatically in the course of the scientific and technological revolution. Also observed was a parallel growth in the theoretical aspects of ecology (the American ecologist R. MacArthur and the Spanish ecologist R. Margalef), which make extensive use of mathematical modeling.

Modern ecology is characterized by the study of processes that encompass the entire biosphere. The interaction between man and the biosphere is studied particularly closely. The main aim of the International Biological Program, which was inaugurated in 1964, was to study the productivity of ecosystems in various parts of the world. In carrying out the program, the methods of determining the productivity of various trophic links in the food chain were standardized. Research on biological productivity was extended through the international Man and the Biosphere program, in which attention is focused on the analysis of the effects of man's activities on the biosphere. Ecologists of different countries are united in the International Association for Ecologists (INTECOL), whose first congress was held in 1974 in The Hague.

Principal tasks and problems. The principal problem faced by ecology at the present time is the detailed study, using quantitative methods, of the fundamentals of the structure and functioning of natural and man-made systems. The study of populations, that is, natural assemblages of individuals of a particular species, who are at the same time elements of the species system and of the biogeocenotic system, has shown that populations have complex hierarchical structures (the Soviet scientist N. P. Naumov). Population ecology studies the spatial distribution of individuals and the age, sex, and ethological (behavioral) aspects of the population, among other things. A central question is that of population dynamics and the related regulatory mechanisms, which are viewed as processes involving intrapopulational mechanisms (for example, competition for food) and biocenotic mechanisms (the effect of predators, parasites, and pathogens and epizootic factors). An important contribution to population ecology was made by the Soviet scientist S. S. Shvarts. The Soviet entomologist G. A. Viktorov showed that the orderly succession of regulating mechanisms is a function of the size of a population. In the study

of the regulation of the size of populations of mammals, much attention is devoted to the analysis of interrelated behavioral, physiological, and hormonal mechanisms. Particular attention is focused on the population dynamics of practically important species, such as agricultural and forest pests, carriers and transmitters of pathogens, and species that are hunted or fished. Many problems in population ecology are solved using model laboratory populations of various organisms. Demographic and mathematical modeling methods are used to evaluate the rate of population growth. The relationship between the genetic composition of a population and its ecological characteristics is one of the problems of evolutionary ecology. Of particular importance is the study of the interaction between populations of different species—competition and predation. In the study of competition, use is made of the concept of ecological niche, for which methods of quantitative analysis are being developed.

Much attention is focused on the study of the structure and functioning of communities (biocenoses) and on the establishment of regularities in the number of species in a community. The relationship between the number and the biomass of different species is also subject to certain rules. The species composition of a community changes in the course of its development (succession); it is also affected by various factors associated with the agricultural activities of man. Another important task is the study of the stability of communities and the ability of communities to withstand adverse conditions.

When studying ecosystems, the opportunity presents itself of quantitatively analyzing the cycle of matter and changes in energy flow accompanying a transition from one feeding level to another. This type of production-energy approach at the population and biocenotic levels makes it possible to compare various natural and man-made ecosystems.

The principal stages in the cycle of matter and the flow of energy are well known for freshwater ecosystems. For some bodies of water, a relationship has been established between the energy that is fixed by green plants within the body of water itself and the energy that comes in with organic matter from terrestrial ecosystems. Such research makes it possible to attempt a solution of the little-studied problem of the exchange of matter and energy between different ecosystems. Ecology has yet to deal with the complex problem of the quantitative evaluation of production processes in the ocean. The extent of primary production in aquatic ecosystems is established from the oxygen output rate or by the incorporation of radioactive tracers in photosynthesis. Despite great procedural complexities, success has been achieved in production-energy research on land.

The cycle of biogenic elements and primary production in the principal types of land ecosystems have been studied. It has been demonstrated that the total volume of primary production on land is approximately double that of the total production of the world ocean and that the productivity of tropical forests is particularly high. The earth's surface is photographed in the visible and infrared regions of the spectrum from spacecraft in order to evaluate the biomass reserves in terrestrial ecosystems. Research on the utilization of organic matter synthesized by autotrophs has shown that on land only a small portion of organic matter is used directly by herbivorous animals, while the bulk of it, in the form of dead plant tissue, is consumed by saprophagous and saprophytic organisms. In addition to feeding links, other links exist between organisms in ecosystems, particularly those involving metabolic products released by organisms into the environment. They are being actively studied in both terrestrial and aquatic ecosystems.

The study of the biosphere as a whole is particularly important, including the determination of primary production and decomposition worldwide and the global cycle of biogenic elements. These problems can only be solved through the concerted efforts of scientists from various countries.

The diversity of the phenomena studied by modern ecology explains its extensive ties with numerous natural and humanistic sciences. Population ecology involves genetics, physiology, ethology, biogeography, taxonomy, and demography. Biogeocenology involves landscape science, biogeochemistry, soil science, hydrology, hydrochemistry, climatology, and other environmental sciences. Under the influence of ecology, many biological sciences have begun examining various aspects of life from the ecological point of view. These include environmental physiology (also ecophysiology or physiological ecology), ecological morphology, ecological cytology, and ecological genetics.

Advances in mathematics, physics, chemistry, and philosophy have had a significant effect on ecology. In its turn, ecology has posed new mathematical problems, especially in statistics and modeling. Ecology has made important contributions to the development of ideas about the systems organization of living matter. Ecology's ties with the humanities—sociology, political economy, jurisprudence, and ethics—are growing significantly. Through the study of agrocenoses ecology is closely linked with the entire range of agricultural sciences. Ecology and biogeochemistry together study the processes of migration in the biosphere of biogenic elements, which limit the production of agricultural products (*see* BIOGENIC ELEMENTS).

Practical importance. At the present stage of the development of human society, with man's increasing influence on the biosphere as a result of the scientific and technological revolution, there has been a dramatic rise in the practical importance of ecology. Ecology must serve as the basis of all measures regarding the utilization and protection of natural resources and the maintenance of the environment in a condition favorable to man (*see* CONSERVATION). An understanding of the basic principles of the transformation of matter and energy in natural ecosystems provides a theoretical basis for the development of practical measures for increasing the quantity and improving the quality of food products produced in the biosphere. The investigation of the natural mechanisms that control the size of populations serves as the basis for the planning and development of measures for controlling the number of economically important species. A knowledge of the fundamental factors of population dynamics is helpful in combating agricultural and forest pests and transmitters and carriers of diseases. Thus, the achievements of ecology make it possible to revise measures against agricultural and forest pests, shifting from attempts to completely eradicate them using broad-spectrum pesticides, which are harmful to the entire biogeocenosis, to the effective control of the number of certain species using primarily biological and agrotechnical methods, with only limited use of chemical methods.

Ecology provides a theoretical basis for the development of measures for the domestication and other forms of efficient utilization of wild plants and animals. The efficient management of fishing, fish culture, and hunting is based on ecological data.

Ecology studies the interaction between agricultural and natural ecosystems and the relationship between cultivated and natural landscapes. One of the most important practical tasks of ecology is the study of the eutrophication of inland bodies of water, occurring as a result of the disruption of their biological and hydrochemical regimes and resulting in such consequences unfavorable to man as the mass proliferation of planktonic blue-green algae, the disappearance of valuable fish species, and the deterioration of water quality. The development of measures for the protection and efficient utilization of nature in the wild, the creation of a network of wildlife preserves, sanctuaries, and national parks, and landscape planning are also carried out on the basis of recommendations developed by ecologists. A highly practical direction is characteristic of human ecology (*see below*: Social aspects).

In developing the national economy, the Communist Party of the Soviet Union singles out as its most important objectives the efficient utilization of natural resources and conservation, the achievement of which requires the broad dissemination of ecological knowledge among all strata of society and the formation of basic scientific and ecological concepts. The responsibility of the Soviet population to respect nature and protect its treasures is written into the Constitution of the USSR.

Principal scientific organizations and periodicals. In the USSR ecological research is conducted at institutes and various organizations of the Academy of Sciences of the USSR, including the A. N. Severtsov Institute of Evolutionary Morphology and Animal Ecology in Moscow, the Institute of Animal and Plant Ecology in Sverdlovsk, the Zoological and Botanical institutes in Leningrad, the Forestry Laboratory in Moscow, the Institute of Geography in Moscow, the Institute of Biology in Novosibirsk,

and the Institute of Biology and Soil Science in Vladivostok. Ecological research is also carried out by the zoological and botanical institutes of the academies of sciences of the Union republics, the Institute of Deserts of the Academy of Sciences of the Turkmen SSR in Ashkhabad, and the All-Union Institute of Plant Protection of the V. I. Lenin All-Union Academy of Agricultural Sciences in Pushkin, near Leningrad.

Research on aquatic ecology is carried out at the Institute of the Biology of Inland Waters of the Academy of Sciences of the USSR in the settlement of Borok, Yaroslavl' Oblast, the Institute of Hydrobiology of the Academy of Sciences of the Ukrainian SSR in Kiev, the Institute of Oceanography in Moscow, the All-Union Scientific Research Institute of Fisheries and Oceanography in Moscow, and the Institute of the Biology of Southern Seas of the Academy of Sciences of the Ukrainian SSR in Sevastopol'. Ecological research is also carried out at scientific institutions and in sanctuaries, hunting preserves, antiplague institutions, health and epidomiological stations, and other antiepidemic institutions.

The main Russian publications that discuss the results of ecological research are *Zhurnal obshchei biologii* (Journal of General Biology; since 1940), *Ekologiia* (Ecology; 1970), *Zoologicheskii zhurnal* (Zoological Journal; 1916), *Botanicheskii zhurnal* (Botanical Journal; 1916), *Biulleten' Moskovskogo obshchestva ispytatelei prirody: Otdel biologicheskii* (Bulletin of the Moscow Society of Naturalists: Biological Section; 1922), *Gidrobiologicheskii zhurnal* (Hydrobiological Journal; 1965), *Okeanologiia* (Oceanography; 1961), and *Biologiia moria* (Marine Biology; 1975). Problems of applied ecology are dealt with in the journals *Lesovedenie* (Forestry; since 1967), *Okhota i okhotnich'e khoziaistvo* (Hunting and Game Management; 1955), *Rybovodstvo i rybolovstvo* (Fish Farming and Fishing; 1958), *Vodnye resursy* (Water Resources; 1972), and *Zashchita rastenii* (Plant Protection; 1956).

The most important foreign periodicals on ecology are *Ecology* (Brooklyn, N.Y.; since 1920), *Ecological Monographs* (Durham, N.C.; 1931), *Journal of Animal Ecology* (Cambridge; 1932), *Journal of Ecology* (London; 1913), *Oikos* (Copenhagen, 1949), *Oecologia* (Berlin; 1968), *Ekologia Polska* (Warsaw; 1953), *Journal of Applied Ecology* (Oxford; 1964), *Internationale Revue der gesamten Hydrobiologie und Hydrographie* (Leipzig; 1908), *Theoretical Population Biology* (New York–London; 1970), and *Limnology and Oceanography* (Baltimore, Md.; 1956).

Articles on ecology also appear in the major natural science journals, such as *Science* (New York; since 1883), *American Naturalist* (New York; 1867), and *Nature* (London–New York; 1869). Periodic collections dealing mainly with survey articles include the *Annual Review of Ecology and Systematics* (Palo Alto, Calif.; since 1970) and *Advances in Ecological Research* (London–New York; since 1962).

Social aspects. The scientific and technological revolution is closely linked with the unceasing growth and expansion of society's industrial activities. This has aroused increasing interest in ecological problems, particularly the following: the direct and indirect effects of industrial activity on the composition and properties of the atmosphere; the thermal regime of the planet; background radiation; the pollution of the world ocean and inland bodies of water; the decrease in freshwater reserves and nonrenewable sources of energy and raw materials; the release into the biosphere of wastes that have not been detoxified or wastes that cannot be treated biochemically; the ecological effects of anthropogenic, particularly urbanized, landscapes; and the effects of ecological factors on man's physical and mental well-being and on the gene pool of human populations.

The social aspects of ecology became the subject of special scientific research in the 20th century. As early as the 19th century, G. P. Marsh, after analyzing the many ways in which man had violated the balance of nature, proposed a program for its protection. A number of 20th-century French geographers (P. Vidal de la Blache, J. Brunhes, E. de Martonne) advanced the idea of the geography of man, which studies phenomena on our planet involving human activity. Man's influence on the geographic landscape and the embodiment of his activities in social space have been studied by representatives of the 20th-century Dutch and French schools of geography (L. Febvre, M. Sorre) and by the constructive school of geography, developed by the Soviet scientists A. A. Grigor'ev and I. P. Gerasimov.

The development of geochemistry and biogeochemistry has transformed man's industrial activities into a powerful geochemical factor, heralding new eras in geology—the anthropogenic era (the Russian geologist A. P. Pavlov) and the psychozoic era (the American scientist C. Schuchert). V. I. Vernadskii's teachings about the biosphere and its transformation into the noosphere are tied in with new views on the geological consequences of the social activities of mankind.

Social aspects of ecology are also the concern of historical geography, which studies the links between ethnic groups and the natural environment, and especially of sociology, particularly social ecology, which studies the interrelations of social groups and the environment. The founders of the Chicago school of sociology (R. Park, E. Burgess, R. D. McKenzie), who formulated one of the first theories of human ecology, or social ecology, showed the relationship between the spatial organization of a city, the location of various social groups, and the mechanisms of economic competition.

The subject matter and status of human ecology are a matter of dispute; human ecology is variously defined as the systematic study of the environment, the science of the social mechanisms of interaction between human society and the environment, or the ecological science emphasizing man as a biological species (*Homo sapiens*). Nevertheless, ecology has significantly changed the thinking of both naturalists and humanists, having given rise to new theoretical approaches and methodological orientations in various sciences and to new ecological ideas. Using a systems approach, ecologists analyze the natural environment as a complex differentiated system whose various components are in dynamic equilibrium. They examine the earth's biosphere as the ecological niche of mankind, linking the environment and man's activities into a single "nature-society" system. They uncover man's influence on the equilibrium of natural ecosystems and pose the problem of controlling and improving man's interrelation with nature.

Ecological ideas are reflected in various proposals to reorient technology and industry. Some are associated with a mood of ecological pessimism and alarmism, with the revival of reactionary romantic Rousseauistic concepts, according to which the main cause of the ecological crisis is scientific and technological progress itself, and with the emergence of such doctrines as limits to growth and steady state, according to which it is imperative to limit considerably or end entirely technological and economic development.

Other ecologists, in contrast to this pessimistic view of man's future and the prospects for the utilization of nature, have proposed a radical restructuring of technology, ridding it of the miscalculations that have resulted in environmental pollution (for example, the program of alternative science and technology proposed by the American researcher D. Gabor and the model of closed industrial cycles developed by the American ecologist B. Commoner), and the development of new equipment and technological processes (transportation, power engineering) that are ecologically acceptable.

The realization of the importance of the social aspects of ecology has resulted in the emergence of ecological economics, which takes into account not only the costs of the utilization of natural resources but also the costs of protecting and rehabilitating the exosphere. It emphasizes not just profitability and productivity but also the ecological basis of technical innovations and ecological control over the planning of industry and the utilization of nature. Key steps in the development of ecological economics were taken by Soviet economists (S. G. Strumilin and others).

The development of ecology has been a powerful force in the emergence of new human values—the preservation of ecosystems, the view of the earth as a unique ecosystem, and a careful approach to all that is living. A tendency toward the ecological reorientation of ethics is evident in various concepts in ethics, for example, A. Schweitzer's teachings about reverence for life, the land ethic of the American ecologist A. Leopold, K. E. Tsiolkovskii's cosmic ethics, and the ethics of the love of life developed by the Soviet biologist D. P. Filatov.

The development of ecological thinking under capitalism conflicts with the absence of adequate mechanisms for the efficient control of the exchange of matter between society and nature. Under these circumstances, the negative consequences of these actions on the biosphere are so imposing that they are referred to as the ecological crisis.

The prerequisites for the rational control by man of his exchange of matter with nature have been created for the first time in a socialist society. Early in its existence, the Soviet government was not always able to devote proper attention to ecological problems, as a result of which certain large-scale industrial measures were not given a comprehensive ecological basis. In contrast to capitalist countries, where ecological measures are unavoidably of a limited nature, the socialist social order makes it possible to carry out systematically comprehensive long-term programs intended to preserve and improve the environment and to overcome the negative ecological consequences of scientific and technological progress.

The global nature of man's influence on the environment calls for international cooperation and the implementation of multinational and intergovernmental measures.

ECONOMETRICS, the study of the specific quantitative regularities and interrelationships of economic objects and processes by means of mathematical and statistical techniques and models. The models used in econometrics yield numerical results on the basis of statistical, forecasting, and planning data. Econometrics is sometimes broadly construed as the modeling of economic processes in general, including abstract theoretical models.

The potential uses of econometrics depend on the degree to which a model reflects the objective laws discovered by economics, on the availability and quality of the data, and on the techniques employed in their evaluation and processing. In some instances, on the other hand, econometrics makes it possible to use factual material in order to concretize and verify theoretical hypotheses and models in the economic sciences.

K. Marx noted the possibility of "mathematically deducing . . . the main laws of crises" from the analysis of such factors as price dynamics and discount rates (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 33, p. 72). Some early attempts at the mathematical formalization of economic and statistical data were made in the 19th and early 20th centuries—for example, V. Pareto's derivation of the hyperbola equation to describe income distribution in the capitalist countries (1897), the works of R. Hooker (Great Britain) on correlation analysis in economics, and the works of the

Russian statistician A. A. Chuprov. But it was not until the 1920's and 1930's that econometrics—owing particularly to the works of H. Moore and H. Schultz (USA)—emerged as an independent scientific school that combined economic theory, statistics, and mathematics. The term "econometrics" was introduced by the Polish economist P. Czompa (1910); it was adopted as a scientific term by the Norwegian economist R. Frisch (1926), who was a founder of the International Econometric Society (1930) together with the Americans I. Fisher and C. Roos.

It was within the framework of econometrics that analytical-statistical models were first developed to express the correlation between an economic process and other factors presumed to influence it. An early example of such a model was the "economic barometer," which was based on the empirically observed tendency of some business indicators to lag behind others. The model that was best known—the "Harvard barometer," which W. Mitchell helped design—proved incapable of predicting the major economic crisis of 1929–33. The failure of purely empirical constructions led to increased interest in the theoretical validation of econometric models; in bourgeois economics, such validation was based on the subjectivist theory of marginal utility, the general theory of equilibrium of the market, and the works of J. M. Keynes.

Analytical-statistical econometric models are usually represented by regression equations, whose parameters are obtained from statistical processing of the data; in most instances the relationship between variables (or their logarithms) is assumed to be linear. Such equations serve to express various functions, including demand (that is, its dependence on such factors as prices, volume of output, income, and taxes), supply, costs, imports, and exports. This category also includes production functions that reflect the technological dependence of output on the expenditure of labor and means of production. The first and simplest production function was formulated by C. Cobb and P. Douglas (USA, 1928); it was subsequently generalized by R. Solow and K. Arrow (USA), who took into account the influence of various factors—for example, scale of production and technological advances. Such regression models can be constructed for individual products, enterprises, firms, and branches, or for the national economy as a whole.

A number of multiple-factor correlation models were developed by J. Tinbergen (Netherlands) in the 1930's and by L. Klein (USA) and R. Stone (Great Britain) in the 1950's. These models describe the statistical interrelation of many variables—including production, ultimate private and state demand, prices, taxes, foreign trade, depreciation and accumulation of capital, and supply of labor power—in the economies of various capitalist countries. Such models include aggregates of hundreds of equations and identities, which increases the difficulties involved in the statistical identification of the objects under study and in the evaluation of the models' parameters.

An example of the type of model that is used to analyze the structure of the national economy is the intersector balance model, which serves to reveal intersector and interregional relations and cost components, as well as the distribution of gross output and final product. The first intersector balance of the national economy was compiled in the USSR under the supervision of P. I. Popov (1925–26). This method was subsequently developed by W. Leontief (USA). R. Frisch was among those who used this method to analyze the flow of money, thus leading to the establishment of the national accounts system adopted by the UN.

In the analysis of economic dynamics, economic growth models are used in order to examine the relationship between consumption and accumulation, with due regard to the influence of various economic factors on this process. An early model of this type, based on Marx' proposed plan of reproduction, was developed by the Soviet economist G. A. Fel'dman (1928). Various models of economic dynamics, especially geared to the analysis of the capitalist cycle, were developed abroad—for example, by Tinbergen, Frisch, M. Kalecki, J. Hicks, R. Harrod, and P. Samuelson.

Econometric methods are based on the extrapolation of trends as revealed by the statistical processing of time series. Inasmuch as extending the forecasting range of economic dynamics reduces the reliability of such methods, it is necessary to resort to expert evaluations of the changes in certain factors that are specifically associated with scientific and technological progress and sociopolitical conditions.

While the various types of models—that is, correlation, balance, and dynamic models—were developed independently of one another, today's aggregate econometric models bring together different types of analytical models in reciprocal association. Such aggregate models are extensively used for economic forecasts and for analyzing alternative economic policies; in the socialist countries they are used for alternative calculations in national economic planning. These issues are discussed in the works of V. S. Nemchinov, B. N. Mikhalevskii, A. G. Aganbegian, A. N. Efimov, E. F. Baranov, L. Ia. Berri, E. B. Ershov, F. N. Klotsvog, V. V. Kossov, L. E. Mints, S. S. Shatalin, and M. R. Eidel'man of the USSR, O. Lange of Poland, and J. Kornai of Hungary.

Many specialists define the task of econometrics as the formalized description and forecasting of economic processes based on the statistical analysis of data; they restrict econometrics to the development and application of analytical models, and sometimes they use only the traditional analytical-statistical, or regression, models. In the 1930's, however, another class of models emerged—namely, the normative models. These models make it possible not only to evaluate the varying structure and dynamics of economic objects but also to select the optimal alternative according to a given criterion of evaluation.

A significant contribution to the development of normative models was made by the Soviet scientist L. V. Kantorovich, who devised linear programming (1939); this enabled him, together with others—such as V. V. Novozhilov and A. L. Lur'e of the USSR and T. Koopmans and G. Dantzig of the USA—to formulate and resolve a broad spectrum of economic problems related to the optimal distribution and utilization of resources. The refinement of optimization methods led to new types of normative models; the works of J. Von Neumann had a major impact in this area.

Types of models vary with the nature of the variables and the form of relationship between them; for example, models may be linear or nonlinear, continuous or discrete, predetermined or stochastic. Depending on the models' specific features, appropriate methods of mathematical programming, operations research, and game theory are applied in each case. In the socialist countries, normative models are widely used in the optimization of national economic planning at all levels (as exemplified by the works of N. N. Nekrasov and N. P. Fedorenko on chemicalization and on the development of the chemical industry in the USSR). In the capitalist countries, optimization methods are applied by individual firms and are also used in the development of state programs. The USSR and other socialist countries are engaged in wide-ranging studies of the internal relationship between normative and analytical models and are developing aggregate models that incorporate both the normative and the analytical type.

Econometric research and development in the USSR are the concern of the Central Economic Mathematical Institute, the Institute of Economics and Management of Industrial Production, and the Institute of World Economics and International Relations of the Academy of Sciences of the USSR, as well as by the institutes of the State Planning Committee of the USSR and of other Union republics, and many branch institutes and higher educational institutions. Works on econometrics have been regularly published since 1965 in the journal *Ekonomika i matematicheskie metody*. The best-known journal abroad is *Econometrica* (since 1933).

ECONOMICALLY ACTIVE POPULATION, the segment of the population employed in the national economy, including persons engaged in private subsidiary farming. In the USSR, the economically active population is the aggregate of all persons engaged in paid or income-producing, socially useful labor.

The statistical criteria of the economically active population vary in different countries primarily according to their inclusion of economically dependent family members working in agriculture or in handicrafts. In some instances, the economically active population includes persons who do not participate in production but who have unearned income. There exists in the statistics of a number of capitalist countries, for example, the concept of the economically independent population, which comprises all persons living on their own income, including those with unearned income and those with pensions.

The percentage of the economically active population is a function of the proportion of working-age persons in the total population (a demographic factor) and of the extent of their employment (an economic-organizational factor). This percentage ranges from 35 to 50 percent in certain countries; in the USSR, it is approximately 48 percent. It is always higher for the male segment of the population. The percentage of the economically active population is considerably larger in socialist and developed capitalist countries than in developing countries. In 1970 the world's economically active population comprised more than 1.5 billion persons.

V. V. POKSHISHEVSKII [29–1844–1]

ECONOMIC AND SOCIAL COMMISSION FOR ASIA AND THE PACIFIC (ESCAP), a regional body established in 1947 by the Economic and Social Council of the United Nations. The purpose of the commission is to promote regional economic development in Asia and to support and strengthen economic cooperation among Asian countries as well as between Asian states and states on other continents. As of Jan. 1, 1980, 35 Asian and Pacific states, together with Great Britain, the Netherlands, the USA, and France, are members of ESCAP; the regional members include India, Pakistan, Afghanistan, Iran, the Mongolian People's Republic, the People's Republic of China, the USSR, and Japan. The commission conducts research; collects, summarizes, and disseminates information and statistical data; and makes recommendations to the governments of ESCAP members on all matters falling within its competence.

The highest organ of ESCAP is the plenary session, which is held once a year. Between sessions, day-to-day work is carried out by standing committees, such as the committees on industry and natural resources, trade, transport and communications, and typhoons. Conferences are held to study problems of, for example, industrialization, planning, statistics, and social development.

The executive organ of ESCAP is the Secretariat, which is located in Bangkok, Thailand. Special regional bodies that operate within the framework of ESCAP include the Council of Ministers for Asian Economic Cooperation, the Asian Industrial Development Council, the Asian Institute for Economic Development and Planning, and the Asian Statistical Institute. [29–1822–1]

ECONOMIC AND SOCIAL COUNCIL (ECOSOC), a principal organ of the United Nations. The Economic and Social Council has 54 members, which are elected by a two-thirds majority of the General Assembly for three-year terms. One-third of the membership is renewed each year.

The main tasks of ECOSOC are to carry out, under the supervision of the General Assembly, the specific functions of the UN in the field of international economic and social cooperation. Article 55 of the UN Charter defines these functions as the creation of conditions of stability and well-being that are necessary for peaceful and friendly relations among nations based on respect for the principle of equal rights and self-determination of peoples.

In order to discharge its responsibilities, ECOSOC is empowered to initiate studies, prepare reports, and make recommendations to the General Assembly, the members of the UN, and the specialized agencies of the UN. The council may call international conferences and prepare draft conventions with respect to matters falling within its competence for submission to the General Assembly. ECOSOC may enter into agreements with specialized agencies of the UN to define the terms of their relationship with the UN and may coordinate the activities of such agencies through consultation with and recommendations to the agencies. It is also empowered to assist the Security Council, furnish the Security Council with necessary information, and perform such other functions as may be assigned by the General Assembly.

Regular sessions of ECOSOC are held twice a year. Each year, the council elects a president and two vice-presidents. Decisions of the council are made by a simple majority of the members present and voting.

The standing and ad hoc committees of ECOSOC include the following: the Economic Committee; the Social Committee; the Committee on Non-Governmental Organizations; the Committee on Housing, Building, and Planning; the Committee on Natural Resources; the Committee for Program and Coordination; the Committee for Industrial Development; and the Committee on Science and Technology.

ECOSOC carries out its duties through various functional commissions, including six statistical commissions, the Population Commission, the Social Development Commission, the Commission on Human Rights, the Commission on the Status of Women, and the Commission on Narcotic Drugs. The Commission on Human Rights has a subcommission on the prevention of discrimination and the protection of national minorities.

The following regional economic commissions have been established under ECOSOC: the Economic Commission for Europe, the Economic and Social Commission for Asia and the Pacific, the Economic Commission for Latin America, the Economic Commission for Africa, and the Economic Commission for Western Asia.

The UN Children's Fund (UNICEF) was created under ECOSOC in 1946 to aid children who are victims of war and to implement measures for the protection of the health of children.

V. I. MENZHINSKII [29–1866–2]

ECONOMIC CARTOGRAPHY, the branch of cartography that is associated with economic geography and with national economic activity. Economic cartography deals with the theory, techniques, and practice of compiling and using economic maps and atlases.

In the USSR, economic cartography was developed in the early 1930's in connection with the increased need for economic maps owing to the rapid development of the republic and regional economies and of the various sectors of the national economy. Such maps were also required to illustrate the achievements of the Soviet economy and for the study of economic geography in educational institutions. Major contributions to the development of economic cartography were made by N. N. Baranskii, A. I. Preobrazhenskii, M. I. Nikishov, and V. P. Korovitsyn.

The evolution of contemporary economic cartography is associated with the growth of theoretical and systematic research in economic geography and cartography, with the use of the achievements of the scientific and technological revolution to solve the problems of planning and forecasting the development of productive forces, and with the formation of territorial-production complexes. It is also related to the fulfillment of long-term economic programs, the combination of sectoral and territorial management of production, and the development of both regional planning and environmental protection. (*See* CARTOGRAPHY.)

ECONOMIC CATEGORY, a theoretical (abstract) expression of actual production relations. The economic category as a means of reflecting the objective world through a system of scientific concepts was first analyzed scientifically by Marxism. In the methodology of political economy, economic categories are treated as stages in the cognition of production relations; they express phenomena and processes characteristic of each historical stage in the development of social production.

Economic categories form a system comprising three sets of categories: (1) general economic categories characteristic of all modes of production, such as the categories division of labor and necessary product; (2) particular economic categories common to a few modes of production, such as the categories of commodity-money relations—commodity, value, and price; and (3) specific economic categories that pertain to a specific mode of production only, such as the categories feudal rent, capital, surplus value, conformity to plan, or fixed capital.

Economic categories are also differentiated according to degree to which they reflect production relations—that is, whether they express the essence of economic processes or phenomena that are nearer the surface of economic life. Examples are value and price, surplus value and profit, conformity to plan and planning, distribution according to labor, and specific forms of wages.

Economic categories are used in the analysis of the parties specific to social production, which are treated in political economy as an embodiment or personification of objective production relations. In commodity production based on the private ownership of the means of production, a reification of production relations takes place, expressed in commodity fetishism: economic categories create a distorted view of reality in which relations between human beings act as relations between things.

Production relations manifest themselves as economic interests in any society. The scientific delineation and analysis of economic categories presupposes their use in studying the interaction and realization of economic interests in a given society.

Economic categories occupy a prominent place in the cognition and application of economic laws, especially under socialism, in which the spontaneous regulation of production through competition is replaced by the planned and conscious use of economic laws in conjunction with the planned management of the national economy.

Political economy as a science and a course of study develops a total and internally consistent system of economic categories and laws for a given mode of production. It is of great importance to delineate and differentiate the initial and basic economic category; this was done with respect to the analysis of the capitalist mode of production by K. Marx, whose ideas were further developed by V. I. Lenin, notably in his theory of imperialism. Marxist scholars in the socialist countries are engaged in working out the economic categories of socialism.

ECONOMIC COMMISSION FOR AFRICA (ECA), a regional body established in 1958 by the Economic and Social Council of the United Nations. The members of the ECA are 49 African states.

The main functions of the ECA include the study of problems of the economic and social development of the African countries, the promotion of the economic development of the African states, and the strengthening of their economic relations both with one another and with other countries. The commission makes recommendations and offers advice to its members on matters falling within its competence. It carries out appropriate studies and compiles surveys, reports, and other types of information.

The highest organ of the ECA is the plenary session, which is held every two years. Between sessions, the highest organ is either the Technical Committee of Experts, which meets once a year, or the Executive Committee, which meets every two years. The executive organ of the ECA is the Secretariat, which is located in Addis Ababa. The commission has the following four subsidiary divisions: one for North Africa, with offices in Tangier, Morocco; one for West Africa, with offices in Niamey, Niger; one for East Africa, with offices in Lusaka, Zambia; and one for Central Africa, with offices in Kinshasa, Zaïre.

The African Development Bank and the African Institute for Economic Development and Planning operate within the framework of the ECA. [29–1827–1]

ECONOMIC COMMISSION FOR EUROPE (ECE), a regional body established in 1947 by the Economic and Social Council of the United Nations. Thirty-two European states, including the USSR, the Byelorussian SSR, and the Ukrainian SSR, are members of the ECE, as are the USA and Canada. The tasks of the ECE include the promotion of trade, especially between states with different social systems; long-range economic projections and planning; scientific and technical cooperation; and the study of environmental problems. The commission makes recommendations to its members on matters falling within its competence.

The highest organ of the ECE is the plenary session, which, as a rule, is held once a year. Between sessions, day-to-day work is carried out by subsidiary bodies, such as committees, subcommittees, conferences of experts, and expert groups. The subsidiary bodies deal with specific sectors of the economy. They include the committees on electric power; ferrous metallurgy; steel; coal; gas; the chemical industry; timber; housing, building, and planning; the development of trade; inland transport; and water problems. Other subsidiary bodies are the Senior Economic Advisers to ECE Governments, the Senior Advisers to ECE Governments on Science and Technology, the Senior Advisers to ECE Governments on Environmental Problems, and the Conference of European Statisticians.

The executive organ of the ECE is the Secretariat, which is located in Geneva. The Secretariat publishes the annual *Economic Survey of Europe*, the quarterly *Economic Bulletin for Europe*, and various surveys and statistical bulletins on individual sectors of the economy. [29–1827–2]

ECONOMIC COMMISSION FOR LATIN AMERICA (ECLA), a regional body established in 1948 by the Economic and Social Council of the United Nations. The Latin American states, the USA, Great Britain, France, the Netherlands, Canada, and Spain are members of the ECLA. The purposes of the ECLA are the development and implementation of measures that promote the economic development of the Latin American states and strengthen economic cooperation both among the Latin American countries and between those countries and states on other continents. For these purposes, ECLA conducts studies of economic, social, and technical problems; collects, summarizes, and disseminates information and statistics on such problems; and offers advice and makes recommendations to its members on matters falling within its competence.

The highest organ of ECLA is the plenary session, which is held every two years. Between sessions, a committee meets periodically to review the commission's work and prepare the ECLA report for the Economic and Social Council. The permanent executive organ is the Secretariat, which is located in Santiago, Chile. It has subsidiary offices in Mexico City; Washington, D.C.; Rio de Janeiro; Montevideo; Bogotá; and Port-of-Spain.

Various subsidiary bodies operate within the framework of ECLA. They include the Central American Economic Cooperation Committee, the Trade Committee, and the High-level Governmental Committee on the Regional Evaluation of the Interna-

tional Development Strategy. The Latin American Institute for Economic and Social Planning and the Regional Center for Demographic Training and Research in Latin America operate under the aegis of ECLA. [29–1828–1]

ECONOMIC COMMISSION FOR WESTERN ASIA (ECWA), a regional body established in 1973 by the Economic and Social Council of the United Nations. The members of the ECWA are 13 Arab entities in Asia.

The purposes of the ECWA include the study of problems of the economic and social development of the countries in the region. The commission makes recommendations to its members, prepares surveys and studies, and disseminates the surveys and studies among its members.

The highest organ of the ECWA is the plenary session, which, as a rule, is held once a year. The executive organ is the Secretariat. [29–1827–3]

ECONOMIC COMPARISONS, INTERNATIONAL, the aggregate of economic and statistical techniques used in comparing various countries' economic indicators (both in physical terms and in terms of value) in close association with the scientific analysis of such techniques. International economic comparisons are employed in objective studies of the levels, structure, and trends of economic development of different countries and can thus reveal production reserves as well as potential efficiency of production.

International comparisons of physical indicators require that both the range of components and their quality be homogeneous. For example, in order to achieve comparability between the steel output of the USSR and the USA, one must take into account the steel produced at US machine-building plants, amounting to 2 or 3 million tons a year. In comparing meat production in the two countries, the official American figures are modified to take into account the production of poultry and lard. In addition, comparable physical indicators are frequently corrected because of obvious qualitative differences; for example, coal output is calculated in terms of hard coal, allowance is made for variations in the sulfur content of extracted petroleum and for the varying proportion of usable matter in mineral fertilizers, and analyses are made of the structure of rolled metal. Thus comparisons are not limited to overall production in millions of tons.

Special difficulties arise with respect to international comparisons of value indicators, which show, for example, gross and final output for different branches of the economy, labor productivity, national income, capital investments, and prime costs. The problem of international comparisons of value indicators can be solved through the consistent use of a single indicator for data from different countries, the reclassification of data from different countries into a uniform system of branch categories, and the conversion of different countries' value indicators to a single currency.

The recalculation of the original data is an essential prerequisite for their comparison; the reason is that such indicators as the national income and the final social product of socialist and capitalist countries are based on fundamentally different concepts. The same applies, albeit to a lesser degree, to international comparisons of industrial and agricultural output and capital investments.

The need for a uniform classification system stems from the fact that different countries classify various branches of production differently. For example, industrial statistics in the USA and in other capitalist countries do not take into account the cost of equipment repairs, which in the USSR is reflected in the value of industrial output; in Soviet statistics, fishing is classified under food industry, while in capitalist statistics it appears under the heading of agriculture.

Conversion to a single currency is a crucial element in comparisons of different countries' value indicators. Various methods can be used to convert national indicators to a single currency. The selection of one or another method for international comparisons depends on the research objective and on the existing statistical base for the countries being compared. Methods that have been used include calculations based on official exchange rates or on a single set of commodities (C. Clark's "international units" and S. Strumilin's "workers' consumption rations"), the use of average and individual prices of representative commodities, and direct weighting of physical indicators in terms of value. Depending on the nature of the available data, several methods are commonly used; the usual procedure is to compute two territorial indexes, correlating the currencies of the countries being compared (parities) and indexes of the volume of their output (first by individual branches or other components of the indicators being compared, with subsequent weighting for the structure of production in the countries involved). Corrections are then made for qualitative differences between products and for the varying degree of specialization of production in the countries being compared.

International comparisons of the interrelated economic indicators of various countries constitute one of the functions of international economic organizations. Thus the Statistical Office of the United Nations makes comparisons of the national accounting systems of the various countries of the world (without converting the indicators to a single currency). The Economic Commission of the Council for Mutual Economic Assistance calculates the socialist countries' national income, industrial and agricultural output, and other economic indicators.

A component of international economic comparisons is the economic and statistical analysis of trends in the economies of various countries—an analysis based on statistical indicators computed on a single conceptual base, albeit without their conversion of a single currency. The data used in such comparisons are published by the United Nations and other international organizations; this makes it possible to analyze the rates, proportions, structural changes, and dynamics of the indicators of production efficiency in various countries.

V. M. KUDROV [29–1860–2]

ECONOMIC COMPETITION BETWEEN THE TWO WORLD SYSTEMS, a major form of global class struggle between the proletariat and bourgeoisie, involving, on the one hand, those states ruled by the working class and, on the other, those states ruled by the imperialist bourgeoisie. Economic competition between the two world systems is based on peaceful coexistence among countries with different sociopolitical systems.

A radical change in the mutual relations of countries belonging to opposing systems in the world economy took place as a result of the ceaseless efforts of the CPSU and the Soviet government to implement the peace program put forward at the Twenty-fourth Congress of the CPSU in 1971. Relations among countries of the two world systems, previously marked by open hostility and even military confrontation, now shifted to a truly peaceful coexistence based on purposeful and mutually advantageous long-term cooperation (*see* INTERNATIONAL ECONOMIC COOPERATION).

The conditions for coexistence and cooperation on a broad front came about through the strengthening of the socialist economy, a fundamental realignment of world forces in favor of socialism, and the recognition by the leaders of several capitalist countries that stable trade and other mutually advantageous relations with socialist countries were both necessary and economically advisable.

Competition between the two opposing socioeconomic systems, which is objective and global, has economic, scientific, technological, political, ideological, and military aspects. While socialism was still weak and was struggling to establish itself, the ruling circles in imperialist countries sought to smother it by means of economic blockades and military intervention. In that period, competition between the two systems was primarily political and military in nature. As the balance of forces changed, as the socialist economy became stronger, as a developed socialist society was constructed in the USSR, and as the socialist countries became better able to defend themselves, competition between the two systems shifted to the areas of economics and of science and technology.

V. I. Lenin pointed out that socialism would decisively influence world developments through its economic successes and through the strengthening of its economy. "The struggle in this field," he wrote, "has now become global. Once we solve this problem, we shall have certainly and finally won on an international scale" (*Poln. sobr. soch.*, 5th ed., vol. 43, p. 341). The new social order conquers the old through its greater social productivity of labor: "those who have the greatest technical equipment, organisation and discipline, and the best machines," Lenin stated, "will gain the upper hand" (*ibid.*, vol. 36, p. 116).

Historically, economic competition can be divided into three stages. During the first stage, which lasted from the October Revolution of 1917 to the formation of the world socialist system, socialism was represented virtually by one country—the USSR. In the second stage, from the end of World War II to the end of the 1960's, the advantages of the world socialist economic system developed and became apparent. In the present stage which began in the late 1960's and early 1970's, the world socialist economic system is becoming more integrated.

The results of economic competition between the USSR and the USA are of major importance in the economic competition between the two world systems: in the mid-1970's the USSR accounted for approximately 50 percent of the industrial output of the socialist countries, and the USA accounted for nearly 40 percent of the industrial output of the capitalist countries. The USSR is responsible for approximately 20 percent of world industrial production. In the 1960's and 1970's the USSR achieved important successes in several areas of economic development, thereby reducing the gap between the levels of development of the USSR and USA.

In 1950 the USSR's national income and industrial output were less than one-third the USA's; in 1976 the USSR's national income was greater than two-thirds, and industrial production was greater than four-fifths, the USA's. In industry the USSR comes closest to the USA in the production of equipment and building materials—that is, in the branches that create the framework of industry. Taken as a whole, the output of industrial means of production in the USSR is approximately 90 percent of that in the USA, and the USSR's output is more than 60 percent of the USA's.

Economically, prerevolutionary Russia lagged 50–100 years behind some of the leading capitalist countries; as early as the 1930's, however, the economy of the USSR, as measured by the volume of output, ranked first in Europe and second in the world. In the mid-1970's the Soviet Union surpassed the USA in the production of coal, petroleum, iron, chromium, manganese ores, coke, steel, pig iron, steel pipes, metalcutting machine tools, main-line locomotives, logs, lumber, cement, prefabricated reinforced-concrete structures and structural members, woolens, butter, and a number of other important products.

Table 1. Average annual growth rates in the economies of selected socialist countries
(percent)

	National income	*Industrial output*	*Labor productivity in industry*
USSR	6.6	8.0	5.3
Bulgaria	7.7	10.4	6.8
Czechoslovakia	4.8	6.2	4.9
German Democratic Republic	4.6	6.2	5.8
Hungary	5.5	6.6	4.9
Poland	7.3	9.1	6.1
Rumania	9.4	12.9	7.3

The USSR nevertheless lags behind the USA in the production of several types of advanced output, including certain types of sophisticated equipment; in the production of automation devices and equipment, electronics equipment, plastics, synthetic fibers, and electric power; in the degree to which production is automated; and in the application of sophisticated production processes. This technological deficiency has caused the USSR to lag behind the USA in the overall technological level of production. The more rapid rates of economic development in the USSR, however, provide a basis for overcoming this lag: between 1961 and 1976 the average annual increase in industrial production in the USSR was almost two times greater than in the USA, 4.4 times greater than in Great Britain, and 1.8 times greater than in France and the Federal Republic of Germany. All countries in the socialist community have shown higher rates of economic growth than the capitalist countries (see Tables 1 and 2).

Table 2. Average annual growth rates in the economies of selected capitalist countries
(percent)

	National income	*Industrial output*	*Labor productivity in industry*
USA	3.4	4.3	3.7
Federal Republic of Germany	3.9	4.4	4.9
France	5.1	4.5	4.4
Great Britain	2.4	1.8	2.8
Italy	4.6	5.5	4.6
Japan	8.8	9.7	8.2

The USSR is overtaking the USA with respect to absolute increase in national income and in industrial and agricultural output. Between 1951 and 1976, for example, the average absolute increase in steel production was 4.5 million tons annually in the USSR, compared with 1.2 million tons in the USA. The corresponding figures were 3.3 and 0.8 million tons for pig iron, 18.5 and 5.1 million tons for petroleum, and 4.4 and 1.2 million tons for cement.

The national income of the member nations of the Council for Mutual Economic Assistance (COMECON) increased by a factor of seven between 1950 and 1976; in the developed capitalist countries national income increased by a factor of approximately 3.3. The corresponding increases in the volume of industrial output were 11.5 and 3.2. Industry in the COMECON countries grew in this period at an average annual rate of 9.8 percent, compared with 4.7 percent in the developed capitalist countries. Although high growth rates in the USSR and other socialist countries in the past often were based on the production of traditional output of a lower technological level than in the developed capitalist countries, the fulfillment of the ninth five-year plan (1971–75) brought the USSR to a higher level, marked by substantial increases in scale of production and by improved quality.

Growing international economic cooperation and the objective demands of the scientific and technological revolution have pushed production efficiency and the rate of scientific and technological progress to the fore in economic competition between the two world systems. Of crucial importance now are indexes that measure scientific and technological progress, the extent to which technology and output are modernized, the quality of goods and their relevance to changing demands, managerial efficiency, the ability of the economy to absorb progressive changes and innovations, the rate of structural changes in production, the rate of circulation, and the payoff periods for production resources.

The socialist countries are already surpassing the capitalist countries with respect to several indexes of efficiency. First and foremost is the superiority of socialism in the use of labor resources and in the absence of unemployment. The Soviet Union was a pioneer in the exploration of space, in the peaceful use of atomic power in electric power production and maritime transport, in the production of several types of hydroelectric power equipment, and in the long-distance transmission of electricity at extremely high voltages. The USSR and the other socialist countries lead in many technologically advanced branches and types of production, although there are still many hidden intraproduction reserves and unresolved problems regarding production quality and the efficient use of all production resources.

The overall increase in production efficiency reflects the objective requirements of the present stage in the progress of productive forces, in which all economic processes are tending to intensify and in which a transition is taking place from extensive to intensive factors of economic development. World socialism, an established integrated economic system, has shown that it can attain not only higher production growth rates but that it can con-

centrate resources in the required direction on a scale unprecedented under capitalism. Countries of the world socialist system have demonstrated their superiority in the planned development of the national economy, in the equitable distribution of income according to labor contributed, in the consistent implementation of social programs on a national scale, and in the creation of a progressive mode of life and a new type of international economic integration that rests on a mutually advantageous foundation and genuinely fraternal cooperation (*see* SOCIALIST ECONOMIC INTEGRATION).

An important part of economic competition between the two world systems lies in various aspects of mode of life and in the mode of life of the population as a whole (*see* MODE OF LIFE). As the scale of production expands, developed socialism implements social programs designed to raise still further the standard of living of the working people and to improve their mode of life.

ECONOMIC COMPULSION TO WORK, the relation, inherent in capitalism, of economic dependence and compulsion between hired workers and capitalists. The economic base of the economic compulsion to work is the capitalists' monopoly of private ownership of the means of production. Deprived of the material conditions for the application of labor and the means of livelihood, workers, though legally free, must sell their labor power to the owners of the means of production and work for the capitalists. The material conditions of labor thus become a means of subordinating another's labor in order to exploit it. The capitalist has command over labor, manages it, determines how long it will last and how intense it will be, and organizes and monitors it. As the scale of production grows, the capitalist transfers these functions to special hired administrators, who manage labor on behalf of capital.

As the owner of the means of production, the capitalist becomes the owner of the product of the workers' labor. The relations of economic dependence and compulsion are reproduced by the entire production process, which is continuous: the product of the worker's labor steadily becomes farther removed from the worker as the property of another and is returned only partially, in the form of wages; the remainder is continuously transformed into means of production and the capitalist's income. Labor is reproduced as hired labor, and the means of production are reproduced as capital. Unlike extraeconomic constraint, which is characteristic of slaveholding and feudal societies and is based on relations of direct subordination, the economic compulsion to work outwardly appears to be a relation of free, legally equal commodity owners, and the labor of workers appears to be voluntary. In reality, the workers' labor for the capitalist is hired slavery.

In the modern scientific and technological revolution, capitalism makes use of science and technology to strengthen and extend economic compulsion. Capital intensifies labor, forces out some workers from production, and demands only an educated and highly skilled labor force. Thus, scientists and engineers are increasingly drawn into the orbit of capitalist exploitation. These facts demonstrate the groundlessness of contemporary bourgeois theories of the "harmony of interests," of "social partnership," of a "collective" or "people's" capitalism, theories that attempt to depict capitalism's objectively inherent relations of dominance and subordination as equal cooperation. Economic compulsion to work cannot be eliminated under capitalism. It can be eliminated only by making the working people owners of the means of production, that is, by abolishing private ownership of the means of production.

L. G. KRYLOVA [29–1876–1]

ECONOMIC COOPERATION BETWEEN THE USSR AND NONSOCIALIST COUNTRIES, an important part of the foreign economic relations of the USSR and a trend in its participation in international economic cooperation. Nonsocialist countries, both industrialized and developing, account for more than two-fifths (44.4 percent in 1976) of the foreign trade of the USSR and a considerable part of the long-term foreign credits granted and received by the Soviet Union.

Various objective factors have led to an expansion of economic cooperation between the USSR and nonsocialist countries. Chief among these, in addition to the need to develop productive forces, is the interrelationship and complementarity of national economies—with respect to natural resources, industrial and scientific-technological potential, knowledge, and experience—in the system of the international division of labor. These factors have made it mutually advantageous for the USSR and nonsocialist countries to exchange goods and services. The expansion of economic cooperation is made possible by the accelerating internationalization of productive forces in the modern scientific and technological revolution.

The USSR has pursued a consistent policy of developing mutually beneficial economic ties with nonsocialist countries and making rational use of the advantages afforded by the international division of labor. This policy, which is true to the nature of socialism, is based on the directives of V. I. Lenin and the decisions of plenums and congresses of the CPSU regarding the need to strengthen the alliance of peoples that are resisting imperialism, to establish closer links with them, to aid and support such peoples in their liberation struggle, and to expand economic cooperation in order that countries of different social systems may peacefully coexist. (*See also* INTERNATIONAL ECONOMIC COOPERATION.)

[29–1882–1]

ECONOMIC COOPERATION OF THE SOCIALIST COUNTRIES, a system of international economic relations that ensures that full use is made of the advantages of the international socialist division of labor.

Unlike the economic cooperation of the capitalist countries, which is marked by a fierce competitive struggle between monopolies, individual countries, and groups, the economic cooperation of the socialist countries is based on the principles of socialist internationalism, full equality, mutual respect, independence and sovereignty, and fraternal mutual aid. The economic cooperation of the socialist countries strengthens the economy of each participating country and reinforces the mutual ties of countries belonging to the socialist community. Under this system, countries are increasingly bound together in the areas of politics, economics, and public life; levels of development are gradually equalized; and the economic power of the world socialist system is increased.

The economic cooperation of the socialist countries dates from the emergence of cooperation between the USSR and the Mongolian People's Republic in the mid-1920's. When the world socialist system took shape after World War II, this process underwent further development. Immediately after the war, the economic cooperation of the socialist countries was primarily concerned with rebuilding and restructuring the various national

economies and with creating the foundations for a modern economy in countries that had inherited a backward material and technical base.

The cooperation of the socialist countries became more varied as their economic, scientific, and technological potential grew. Improvements were made in the cooperative system, which was based on the planned regulation of international economic relations. In addition to bilateral economic cooperation, there was continuous development of multilateral economic cooperation among the socialist countries, enabling them to deal more effectively with important economic problems. The Council for Mutual Economic Assistance (COMECON), established in 1949, and the International Bank for Economic Cooperation, created in 1963, were instrumental in further developing and improving cooperation.

Beginning in the early 1970's, economic cooperation among the COMECON member nations has been based on the Comprehensive Program for Socialist Ecónomic Integration, adopted at the Twenty-fifth Session of COMECON in 1971. This program has made it possible to increase cooperation among the COMECON member nations in order to collectively resolve common socioeconomic problems, to jointly develop natural resources, to carry out major construction projects designed to meet the needs of all the interested countries, and to develop long-term international cooperation among enterprises and branches of industry.

At present, the consistent use of the advantages of economic integration makes it possible to coordinate the COMECON member nations in their efforts to jointly resolve problems involving the expanded extraction and production of the major types of raw materials, fuel, supplies, machine-building output, food, and consumer goods. It also facilitates the development of transportation in accordance with long-term special-purpose programs, worked out jointly, and leads to more closely coordinated and united efforts among the COMECON member nations in the area of scientific and technological progress (*see* SCIENTIFIC AND TECHNICAL COOPERATION OF THE SOCIALIST COUNTRIES).

As the socialist countries become integrated, national economic complexes take shape and interact with one another in a highly sophisticated way; it is against this background that the socialization of socialist production develops on an international scale.

As the international socialist division of labor in various branches and areas of the economy increased, stable international relations were established—notably in the areas of production, science, and technology—that reflected the socialist integration and internationalization of the economic life of socialist countries. As economic cooperation developed, international specialization and cooperation of production and scientific and technical cooperation became more widespread and substantial. Economic organizations and associations created by the COMECON member nations are becoming more active. Increased economic cooperation of the COMECON member nations in all areas is manifested in the growing trade among the countries, which more than doubled in volume between 1971 and 1976 and amounted to 79.2 billion rubles in 1976. Trade among the COMECON countries represented about 56 percent of their total commodity turnover (*see also* WORLD SOCIALIST MARKET).

In accordance with agreements concluded while coordinating national economic plans, the exchange of goods produced by the machine-building industry will be developed at an especially rapid rate. The cooperation of COMECON countries with other socialist countries is expanding on a multilateral and bilateral basis. (*See also* INTERNATIONAL ECONOMIC COOPERATION.)

ECONOMIC CRISIS, a phase in the capitalist cycle in which the basic proportions of reproduction that have been disturbed during the development of the capitalist economy are forcibly restored. Economic crises are manifested in such economic disruptions as an absolute decline in production, a curtailment of capital investment, a rise in unemployment, an increase in the number of bankruptcies, and a fall in the price of stocks.

Economic crises are caused by the basic contradiction of capitalism—the contradiction between the social character of production and the private capitalist form of appropriation of the results of production. Division of labor, specialization of production, and cooperation in industry unite capitalist enterprises in a single economic mechanism; in order for the mechanism to function normally, certain proportions must obtain between branches of the economy, between the production of the means of production and the production of consumer goods, and between the accumulation of capital and consumption. The dominance of private property, however, generates anarchy of production, fierce competition, and the exploitation of labor by capital, which result in the continual disturbance of the proportions of reproduction. Some of these disturbances pass away of their own accord, but others intensify and accumulate.

The disproportions of reproduction that arise as the economy develops are always accompanied by disturbances of the proportions between capital accumulation and consumption.

The tendency of capital toward self-expansion and the race for profits require that the growth of income and consumption of the working people slow down or even come to a halt. The resulting contradiction between production and consumption builds up pressure, reaches the bursting point, and becomes, as a rule, the direct cause of an economic crisis. "The contradiction between production and consumption that is inherent in capitalism is due to the tremendous rate at which production is growing, to the tendency to unlimited expansion which competition gives it, while consumption (individual), if it grows at all, grows very slightly. . . . The productive forces of society increase without a corresponding increase in consumption by the people, without the employment of these productive forces for the benefit of the working masses" (V. I. Lenin, *Poln. sobr. soch.*, 5th ed., vol. 4, pp. 158–59).

Since commodity production exceeds the narrow bounds of the effective monetary demand of the population, an economic crisis assumes the character of general overproduction and an overaccumulation of capital. The economic crisis completes one capitalist cycle and paves the way for the next by equalizing the disturbed proportions between capital accumulation and consumption and between the production of the means of production and the production of consumer goods. Economic crises exacerbate class contradictions, since the misfortunes they bring with them are borne primarily by the working people. This exacerbation intensifies the class struggle, in which the working people attain greater class consciousness, organizational maturity, and solidarity.

Economic crises result in enormous economic losses to society, since a considerable part of the physical plant stands idle and hundreds of thousands or even millions of working people lose their jobs.

The onset, depth, and duration of an economic crisis depend above all on the extent to which the basic economic proportions of reproduction have been disturbed during times of economic upsurge. In addition, economic crises may become self-generating, since they are usually accompanied by a decline in the purchasing power of the working people, brought about by increased unemployment and reduced work time; this decline further complicates the sale of commodities and hinders the restoration of a temporary balance between capital accumulation and consumption.

Economic crises most graphically demonstrate the profoundly contradictory character of capitalist production, which "must, on the one hand, develop productive forces as though it were not production on a limited social basis and must, on the other hand, develop them within this limitation. This paradox is the deepest and innermost cause of crises and of the contradictions that disrupt bourgeois production. Bourgeois production must operate within the framework of these contradictions, which, even when

cursorily and superficially examined, show it to be a historically transitory form" (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 26, part 3, p. 81).

Although there is a single cause for economic crises, each crisis has its own specific features, stemming from the concrete historical conditions under which it develops. An economic crisis reflects the characteristics of the age, the level of development of capitalism, and an entire complex of economic and political factors operative in a given country at the moment the crisis occurs.

Periodic economic crises began with the crisis of 1825 in Great Britain, where capitalist production relations first developed. The next economic crisis was the crisis of 1836, which gripped Great Britain and the USA—two countries with close economic ties. Next came the crisis of 1847, which affected virtually all European countries and assumed the character of a world crisis.

The first worldwide economic crisis occurred in 1857; for nearly every country this crisis proved to be the deepest it had experienced since embarking on the capitalist road of development. In the USA, pig iron production declined 20 percent, and cotton consumption 27 percent. In Great Britain, the shipbuilding industry was hit hardest, with output dropping 26 percent. In Germany the consumption of pig iron declined 25 percent, and in France pig iron production and cotton consumption both declined 13 percent. In Russia pig iron production declined 17 percent, and the production of cotton textiles 14 percent.

The economic crisis of 1866, although rather severe in Great Britain, did not significantly affect other countries.

The next world economic crisis, which began in Austria and Germany in 1873, was the longest in the history of capitalism, reaching its greatest extent in 1878 when it spread to Great Britain.

The economic crisis of 1882 affected primarily the USA and France; in the crisis of 1890, the greatest economic upheavals occurred in Germany, the USA, and France.

The crisis of 1900–03 represents a turning point between the age of laissez-faire capitalism and the age of imperialism. The principal victims of the crisis were the USA and Germany; Great Britain and France were affected to a lesser extent. The economic situation was serious in Russia, where the crisis coincided with a crop failure.

Bourgeois ideologists hoped that with the advent of capitalist monopolies, which organized production at their enterprises in a planned fashion, economic crises would disappear or at least become less severe, but this was not to be. The first economic crisis of the age of imperialism—the crisis of 1907—proved no less destructive than its predecessors. The US economy was hit hardest. In the article "Marxism and Revisionism," V. I. Lenin wrote that the crisis of 1907 offered striking proof that crises remained an inevitable part of the capitalist system. He also pointed out that in the age of imperialism "the forms, the sequence, the picture of particular crises changed" (*Poln. sobr. soch.*, 5th ed., vol. 17, p. 21).

The economic crisis of 1920–21 affected primarily the USA and Great Britain.

In 1929 the world was plunged into its most serious economic crisis, which lasted until mid-1933 and shook the entire capitalist system to its very foundations. During this crisis, production declined 46 percent in the USA, 24 percent in Great Britain, 41 percent in Germany, and 32 percent in France. The value of the stocks of industrial companies declined 87 percent in the USA, 48 percent in Great Britain, 64 percent in Germany, and 60 percent in France. Unemployment reached colossal proportions. According to official data, in 1933 there were 30 million unemployed in 32 capitalist countries, including 14 million in the USA.

The world economic crisis of 1929–33 showed that the contradiction between the social character of production and the private form of appropriation of the results of production had become so acute that the capitalist economy could no longer function normally. State intervention in the economy was required, and the government found it necessary to influence spontaneous processes in the capitalist economy in order to avert upheavals; this policy accelerated the transformation of monopoly capitalism into state-monopoly capitalism.

The long-term planning of economic growth by the state that took place in many capitalist countries after World War II, as well as the efficient regulation of the economy, which was designed to forestall or mitigate cycles, had a certain stabilizing influence on the development of capitalist countries. The signs of economic crisis were nevertheless clearly apparent in this period in the USA, Great Britain, Canada, the Federal Republic of Germany, and Italy.

In most other capitalist countries, the cumulative contradictions of expanded capitalist reproduction were resolved in slowdowns of economic activity and a sharp decline in economic growth, accompanied primarily by a curtailment in the production of the means of production and a deceleration of capital accumulation. In the three postwar decades economic crises recurred most frequently in the USA, in 1948–49, 1953–54, 1957–58, 1960–61, 1969–71, and 1973–75. Industrial production declined, respectively, 17 percent, 9 percent, 13 percent, 7 percent, 8 percent, and 13 percent.

The first postwar global economic crisis, which began in late 1957 and continued until mid-1958, affected numerous capitalist countries, including the USA, Great Britain, Canada, Belgium, and the Netherlands. Industrial output in the developed capitalist countries declined 4 percent, and the army of the unemployed reached nearly 10 million.

The relatively stable economic development of several capitalist countries in the 1950's and 1960's fostered the development of bourgeois and revisionist theories according to which it is possible for capitalism to develop without crises by improving the techniques used in the state regulation of economic processes. Capitalist reality soon refuted these theories, however. In the capitalist system of the early 1970's an entire series of disturbances of the process of reproduction arose, bringing on the next worldwide economic crisis, which began in late 1973 in the USA and affected virtually the entire capitalist world in 1974 and 1975.

With respect to the number of countries affected and in its duration, depth, and destructive force, the crisis of 1973–75 considerably surpassed the world economic crisis of 1957–58 and in a number of respects resembled the crisis of 1929–33. Industrial production declined 13 percent in the USA, 20 percent in Japan, 22 percent in the Federal Republic of Germany, 10 percent in Great Britain, 13 percent in France, and 14 percent in Italy. In a single year—December 1973 to December 1974—the stock market fell by 33 percent in the USA, 17 percent in Japan, 10 percent in the Federal Republic of Germany, 56 percent in Great Britain, 33 percent in France, and 28 percent in Italy. The number of bankruptcies in 1974 exceeded those in the previous year by 6 percent in the USA, 42 percent in Japan, 40 percent in the Federal Republic of Germany, 47 percent in Great Britain, and 27 percent in France. By mid-1975 there were 15 million unemployed in the developed capitalist countries. Another 10 million were either working a shorter work week or had been laid off. The real income of the working people declined everywhere. In the USA, for example, the total real income of the working people, which had grown by an average of approximately 3 percent a year between 1950 and 1970, declined by 6 percent between 1973 and 1975.

The world economic crisis of 1973–75 was unusually severe and long because it involved high rates of inflation in all capitalist countries, currency and energy crises, and a worsening of ecological and food problems. The economic crisis of 1973–75 demonstrated the limited ability of the bourgeois state to regulate spontaneous economic processes and the cyclical dynamics of the economy. The inability of capitalist governments to avert and resolve crises testifies to the crisis of state anticyclical regulation in the 1970's. Because of the significantly higher level of socialization of production and the greater internationalization of economic life, the forms and methods of anticyclical regulation developed immediately after the war ceased to be effective in the 1970's. The basic contradiction of capitalism was once more manifested in acute form.

Economic crises demonstrate the disparity between the production relations of bourgeois society and its productive forces and reveal the transitory nature of the capitalist mode of production, which can develop only by periodically squandering material and human resources. Economic crises convince the working people of the need to struggle for a new social order free from crises, unemployment, and exploitation—that is, the need to struggle for socialism.

IU. N. POKATAEV [29–1855–3]

ECONOMIC EFFICIENCY, the ratio between the results of production—output and material services—on the one hand and expenditures of labor and the means of production on the other. Under socialism, economic efficiency is a key index of economic development. For the capitalist entrepreneur, expenditures take the form of fixed capital stock and circulating productive capital advanced by him, and results take the form of profits. Comparisons of expenditures and results based on report and statistical data for the various branches of the economy and for the national economy as a whole are used in the management of capitalist firms, whose primary motive is the desire to maximize profits.

[29–1837–1]

ECONOMIC EFFICIENCY OF CAPITAL INVESTMENTS, an indicator that provides a picture of the planned connections and quantitative relations between the expenditures of socialist society for expansion and simple reproduction of fixed capital stock and the results obtained. The direct result of capital investment is that production capacities and nonproduction facilities are put into operation; the eventual result is a growth in output and material services and, ultimately, a growth in national income.

The theories and techniques devised by Soviet economists for determining the economic efficiency of capital investments provide a basis for selecting the optimal alternatives of capital investments when drawing up long-term and current (annual or quarterly) plans and plans for specific projects; they play a direct role in the management of enterprises (associations), branches of the economy, and integrated programs with particular goals for economic development.

Between 1951 and 1976 the USSR invested 1.46 trillion rubles, and 1.351 trillion rubles' worth of fixed capital stock became operational. In that same period the total fixed assets (production and nonproduction) increased eightfold, and net output (national income) increased sevenfold. Capital investment in production fixed assets accounts for two-thirds of all investment.

The effect (result) of capital investments in production for the national economy, branches of the economy, and subbranches that keep the appropriate records is manifested in the growth of the gross product, final product, and net product (national income), expressed in terms of value and in physical terms. Efficiency is measured, however, by the ratio of the result (output) to the expenditures (investments) needed to produce the result.

In branches, subbranches, and enterprises (associations) that do not calculate net output (national income), profit is used as an index of the effect, and efficiency is taken as the ratio of profit to the value of capital or as the ratio of the growth in profit to the growth in the value of capital (or of capital investment). This index does not give a quantitative description of the overall economic efficiency of capital investments, because it does not include a considerable part of the net product, such as wages or the social consumption funds; it does make possible an evaluation of the dynamics of capital investment.

The effect of capital investments in the nonproduction sphere is expressed in the growth of services that meet nonproduction sociocultural needs, such as housing, consumer services, education, and health care. Efficiency is measured as the ratio of physical results—for example, residential housing space, the number of places in schools, or the number of hospital beds—to expenditures (investments).

Determining the absolute (general) efficiency of capital investments—the ratio of effect to expenditures—is of great importance in planning the reproduction of the social product and subjecting it to analysis, especially in view of the need to increase the efficiency of social production under conditions of full employment of the work force and an increasing use of natural resources (*see* ECONOMIC EFFICIENCY OF SOCIALIST PRODUCTION). In branches of the economy and in enterprises, indexes of the capital-output ratio and capital productivity are used; these are compared with indexes of the prime cost of production. A rise in the capital-output ratio or a decline in capital productivity may be offset by a decline in current expenditures and be recouped within a prescribed period. This is the esential feature of the problem of payoff on capital investment (*see* PAYOFF ON CAPITAL INVESTMENT).

The economic efficiency of capital investments in both the production and nonproduction spheres depends to a considerable extent on several factors: the lowering of actual expenditures for construction, improvements in construction quality, the reduction of construction time, the degree to which production capacities are developed, and the attainment of projected economic indexes.

A distinction is made between the planned and actual efficiency of capital investments. Planned efficiency is set by the plan, which has taken into account potentials for using internal production resources, for increasing the productivity of labor, for lowering the material-output and capital-output ratios, for achieving technological progress, and for increasing the scale of production. A value is assigned to planned efficiency on the basis of the ratio of the planned effect to expenditures. Actual efficiency is determined by comparing report data on expenditures with data on the effect; these data are compared for the national economy, branches of the economy, and enterprises.

The comparative economic efficiency of capital investments is used to make the best choice among possible capital investment alternatives in overall planning and the planning of specific projects, with a view to turning out products that will meet a given demand. Capital investments and current expenditures are compared, variant by variant, and the investments most attractive in terms of payoff time and discounted expenditures are selected. In order to calculate comparative efficiency, it is important to determine correctly the standard, or normative, coefficient of efficiency, which is inversely proportional to the standard payoff time.

A planned standard of comparative efficiency is used to arrive at an annual figure for capital investments and to add them in with current expenditures. The planned standard represents the minimum permissible level of economy on current costs or minimum permissible level of profits, in relation to a given investment, at which that investment becomes acceptable. The Standard Methods for the Determination of the Economic Efficiency of Capital Investment permit branches of the economy to adjust the standard coefficient of comparative efficiency for the national economy that appears in their instructions for determining economic efficiency; such adjustments take into account the particular features of the various branches of the economy or regions of the country, such as differences in wages, in the technological makeup of assets, in indirect economic effects, and in climate.

The Standard Methods call for a method of discounting based on compound interest to relate expenditures made at various times to a particular period. The planned standard for discounting reflects the average accumulation of capital for the national economy in relation to production assets and is therefore in accordance with the rate of growth of social production. Capital investment at the end of the first year, together with its increment, becomes $C(1 + B)$, which, when reinvested, becomes $C(1 + B)(1 + B)$, or $C(1 + B)^2$, by the end of the second year; by the end of the nth year the figure becomes $C(1 + B)^n$.

Investments in the nth year may be converted into those of the

first year by dividing the later figure by $(1 + B)^n$ or multiplying it by $1/(1 + B)^n$. In this method of discounting the optimal investments is that in which the total discounted capital investments and current expenditures are, other things being equal, the lowest; a common measure can then be applied to investments made at different times, and the investments can be compared and added.

T. S. KHACHATUROV [29–1837–2]

ECONOMIC EFFICIENCY OF NEW TECHNOLOGY, an indicator that characterizes the results for the national economy and the economic suitability of producing and using new technology.

A distinction is made between fundamentally new technology, which has just been introduced, and new technology, which has been introduced to an insufficient extent. Fast reactors, lasers, cryogenic power lines, and ground-effect machines are examples of fundamentally new technology; computers and automatic transfer lines with numerical program control are examples of new technology. Fundamentally new technology requires large capital investments for debugging, for converting to mass production, and for advancing into new areas of application. However, such technology promises a substantial result in the future. New technology requires less investment for debugging and refinement, and expenditures for production depend on the scale of possible introduction. The result of such technology may be obtained in a shorter period of time and depends on the scale of introduction.

The methods used to determine the economic efficiency of new technology are the same as the methods used to determine the economic efficiency of capital investments. The methods are based on a comparison of expenditures for new technology and the result obtained from the technology. A distinction is made between the absolute, or general, efficiency and the relative efficiency of new technology. Absolute efficiency is measured as the ratio of the result obtained from new technology—for example, a growth in output, a reduction in the prime cost of production, or an increase in profits—to the expenditures for the development and introduction of the technology. Relative efficiency is used to select the best available variant of new technology by determining the payoff period for capital investment or by comparing discounted expenditures for different variants.

In order to determine the economic potential of the introduction of new technology—that is, the result obtainable from the maximum number of units of new technology under optimum conditions—and the actual or possible scale of introduction for individual years, the following are calculated: the reduction in expenditures for production of new technology that is equivalent in capacity to old technology; the growth in output that may be obtained as a result of using the new technology; and the increase in the profits of the producer and the user of the new technology due to the increase in output, the reduction in the prime cost of production, or changes in prices.

The conversion to the manufacture of new producer goods entails additional expenditures on the part of the producer, especially when sufficient experimental testing and other preparatory work have not been done. Initially, such additional expenditures may result in lower profits or even in losses. The user may also bear additional expenditures owing to the conversion to new technology. The additional expenditures are compensated by a subsequent increase in profits as production is increased and prime cost is reduced. Moreover, a temporary reduction in profits or temporary losses may be offset by bank credit. The price of new technology is set at a level that would motivate the producer to fabricate the technology and the user to adopt it.

Besides indexes of value, certain other indexes may be used to evaluate the economic efficiency of new technology. These include the release of labor power, the facilitation and sanitization of working conditions, a reduction in the consumption of scarce materials, and improvements in the quality and reliability of products. Such improvements may not always be reflected in the value and prime cost of the products.

A distinction is made between the planned and the actual economic efficiency of new technology. Planned efficiency is determined on the basis of planning data pertaining to the amount of output, the amount of capital investment, prime cost, and the payoff on capital investment. Data pertaining to the planned and actual economic efficiencies of new technology are used to determine desirable trends for the development of the technology and to plan the introduction of the technology. If the price of new technology is not known when the efficiency of the technology is being planned, the expenditures for the technology may be determined on the basis of estimates of production outlays or, in the absence of such estimates, on the basis of consolidated norms and analogs.

The actual economic efficiency of new technology is measured as the ratio of the reduction in the prime cost of production or of the increase in profit due to the introduction of the technology to the capital investments for the introduction of the technology. The expenditures for new equipment include expenditures for the delivery and installation of the equipment, for the construction of working areas, and for the augmentation of the circulating productive capital associated with the introduction of new technology. Savings in capital investments due to the release of working areas and savings in circulating productive capital are deducted from the expenditures for new equipment. The data obtained are compared with the expenditures that would be required for the old technological base and for the same amount of output. In addition to capital investments, the prime costs of production associated with the new and old technologies are also compared. If the introduction of new technology entails an increase in output, the prime cost is scaled to the increased output; the constant portion of the expenditures and changes in the prime cost are taken into account.

ECONOMIC EFFICIENCY OF SOCIALIST PRODUCTION, one of the most important indicators of socialist economic development; the ratio of the useful result (effect) to the expenditures—determined for the national economy, branches of the economy, and individual factories—required to achieve that result. Several indexes of the economic efficiency of socialist production may be determined by comparing types of expenditures for the production of output or for the provision of material services with the useful effect. Such indexes are helpful in the quantitative and qualitative analysis of the economy as a whole or of its various subdivisions and are used in the planning and day-to-day management of economic activity.

Indexes of economic efficiency are conventionally divided into three groups. The first comprises general indexes of economic efficiency, the most important of which is the growth of the social productivity of labor. This growth may be expressed quantitatively in the growth of output and in absolute savings of living and embodied labor, measured in terms of value and in physical terms. The results of production are most completely represented in the final social product and national income (net output) (*see* TOTAL SOCIAL PRODUCT). Overall profitability is also considered a general index.

The second group of indexes consists of the basic indexes of economic efficiency in the use of such production resources as living labor, fixed production assets, expenditures of materials, and capital investments. These indexes, which are computed on the basis of national income (net output), include the productivity of living labor (labor input), capital-output ratio (capital productivity), consumption of materials (materials-output ratio), and return on capital investments (capital intensity).

The third group of indexes comprises technological-economic indexes of efficiency in the use of resources. These indexes are used in the analysis and planning of several aspects of the production process and in the calculation of factors of production growth at enterprises, branches of industry, and in agriculture, construction, trade, and transportation. The third group of indexes includes individual output; coefficients of the use of the means of labor and of the capacity of machinery units; expenditures of raw materials, supplies, fuel, and energy per unit of output; and payoff period, discounted expenditures, and capital investments per unit of output.

Depending on the method of calculation used, indexes of the productivity of labor play various roles in the system of indexes of the economic efficiency of socialist production. Growth in the productivity of living labor, when measured as the ratio of the final results of production and the total expenditures of living and embodied labor, is a general index of economic efficiency (and therefore belongs in the first group), since it most completely reflects the results of the interactions between material (physical) and subjective (social) elements of the productive forces. Individual output, or the productivity of living labor, measured as the ratio of the results of production and expenditures only of living labor, is an important instrument for analyzing and planning economic efficiency in the use of labor resources (and therefore belongs in the second group). For this reason, both indexes are used simultaneously in national economic planning.

None of the indexes listed above, considered separately, sufficiently takes into account expenditures, effect, or both taken together. As a rule, the rates and directions of change reflected by these indexes fail to coincide, and it is therefore virtually impossible to use them to make clear-cut economic decisions. A steady growth in national income and the productivity of social labor, for example, suggests an increase in economic efficiency of production, but a drop in capital-output ratio and profitability indicates that production is becoming less efficient. The application of such generally accepted indexes of relative economic efficiency, as minimum discounted expenditures is limited by the nature of the indexes being compared.

Although it is necessary to select a criterion of economic efficiency and to develop an appropriate general indicator, many theoretical complexities are involved; Soviet economic science has therefore devised a variety of approaches to solve these problems. One of the most common viewpoints maintains that the criterion of the economic efficiency of socialist production is the amount of work time saved, or saving of the expenditure of aggregate (living and embodied) labor per unit of output (*see* ECONOMY OF TIME, LAW OF).

The level of social productivity of labor (A) coincides with the national economic efficiency of production (E) and is, at the same time, a general index of efficiency: $E = A = R/(L_l + L_e)$, where R represents the final results of production (output volume expressed in physical terms) and $L_l + L_e$ represents expenditures of aggregate (living and embodied) labor, using a single unit of measure. The expression of the final results in terms of, for example, the total gross social product, the final social product, or national income (net output) constitutes a modification of the index.

Of practical interest is the general index of efficiency in the use of resources, calculated as the ratio of national income in fixed prices to production assets and to expenditures not just of labor consumed but of all labor involved in production. Many economists regard a growth in profits, an increase in net profit or profitability, or a rise in the level of the people's well-being as a criterion of efficiency.

In a developed socialist society, the social development of society and increased social efficiency ultimately take precedence over efficiency of production. The most general criterion of social efficiency is the improvement of the living standard of the population and the comprehensive development of the individual. The standard of living can be expressed through a system of indexes that includes growth in real incomes and the per capita consumption of staple foods. It is not always possible, however, to take direct account of or to quantify many social changes, especially in the intellectual life of the individual or in social relations; in such cases, indirect methods must be used. The effect of changes in working and living conditions, for example, can be evaluated by looking at the life expectancy of the population and at reductions in infant mortality, industrial accidents, and occupational diseases.

The CPSU has developed an economic strategy that emphasizes increasing the economic efficiency of socialist production and seeks to develop intensively all branches of the national economy and to intensify all production processes. By the early 1970's, extensive factors—the hiring of additional manpower and the expansion of production capacities through the construction of new enterprises—had essentially been exhausted in the USSR; it consequently became necessary to make more efficient use of the nation's great industrial and technological potential in order to increase the production of national income and the final social product.

"The present and future development of the nation requires all-around intensification of production, acceleration of scientific and technological progress, and growth in the productivity in labor, all of which are crucial factors in increasing the efficiency of production and raising the standard of living of the population. First and foremost, the return on every unit of material, labor, and financial resources must be increased, and production assets must be used efficiently" (*Materialy XXV s"ezda KPSS*, 1977, p. 126).

The party's economic strategy places particular emphasis on accelerating the growth of the social productivity of labor. During the ninth five-year plan alone (1971–75), the productivity of labor in the national economy increased by 23 percent; this figure is roughly equivalent to a saving of 20 million man-years. An increase in the productivity of labor accounted for 84 percent of the growth of production in industry, 78 percent of the increase in construction, and the entire increase in agriculture.

When the role of economic controls in the planning and management of the national economy was increased, enterprises (associations) were more strongly motivated to use production resources more efficiently and to increase profitability. Approximately 500 billion rubles in profits were obtained in the ninth five-year plan, an increase by a factor of 1.5 over the eighth five-year plan. The implementation of the economic policy of the CPSU, which is aimed at intensifying social production, involves improvements in economic management and the scientific elucidation of pressing problems relating to increased economic efficiency of socialist production. (*See also* OPTIMALITY CRITERION, INTENSIFICATION OF PRODUCTION, ECONOMIC EFFICIENCY OF CAPITAL INVESTMENTS, and ECONOMIC EFFICIENCY OF NEW TECHNOLOGY.)

ECONOMIC GEOGRAPHY (also economic and social geography), the social science that studies regularities, or patterns, in the location of social production and the conditions and particulars of its development and location in various countries and regions. The regional aspect of social reproduction under specific sociohistorical conditions is the subject of research in economic geography.

Economic geography studies problems in the regional distribution of the economy in close relationship with the operation of objective economic laws. Of major importance are the integrated and comprehensive examination of investigated phenomena, the analysis of the sociohistorical conditions of countries and regions, the consideration of natural conditions and resources, and the primarily geographical aspect of all research. Unlike industrial branch economics, which studies the location of the productive forces of a given branch of industry, economic geography also studies the regional structure of the economy as a whole.

Economic geography is part of the system of geographic sciences (*see* GEOGRAPHY) and has particularly close ties with physical geography. Economic geography's ties with the other natural sciences that study natural conditions have been strengthened as the importance of the ecological problem has grown; this development reflects the general reorientation of contemporary geography toward ecology. Economic-geographical research is an important part of the integrated and comprehensive study of the interaction of nature and society, which is of interest to both the natural and the social sciences.

Economic geography is also interconnected with the historical sciences (particularly with historical geography), the history of national economies, demography, ethnography, and economic cartography. It also occupies an important place in area studies and military geography.

One of the most important concepts of economic geography is the geographic (territorial) division of labor (including the international division of labor), which results in the formation of economic regions in a country. In turn, the system of economic regions is the basis of the territorial structure of a country's national economy. Other fundamental concepts of economic geography include location of productive forces, economic-geographical location, and the territorial-production complex.

Economic geography is divided into general economic geography, the economic geography of branches of the economy, the geography of the world economy, population geography, political geography, and regional economic geography. General economic geography studies regularities in the location of production in general and of individual branches of production. The best-developed subdivisions of the economic geography of branches of the economy are industrial geography, agricultural geography, and transportation geography. The geography of social services, recreational geography, and natural resources geography are currently emerging as well-defined subdivisions. Because of the special role of the population as the producer and final consumer of material goods and services, population geography has a synthetic character rather than an orientation toward branches of the economy. Regional economic geography investigates existing countries and regions and incorporates elements of all subdivisions of economic geography. General and regional economic geography are inseparably related: on the one hand, general regularities achieve local manifestation within individual regions; on the other hand, the analysis and synthesis of regional combinations make it possible to elicit regularities in economic location.

Differences in regularities of location of production, caused by differences in the socioeconomic systems of various countries, necessitate the division of economic geography into the economic geography of socialist countries and the economic geography of capitalist countries.

The economic geography of socialist countries not only describes and explains economic-geographical phenomena and processes, it also strives to make recommendations for improving the location of production and the territorial structure of the economy. By contributing to the scientific substantiation of the planning of the national economy, economic geography helps solve the problem of ensuring maximum satisfaction of the growing needs of society while simultaneously maintaining ecological stability. Solution of the problem is facilitated by the public ownership of the means of production and by a planned development of the national economy.

The influence of socialist production relations on the development of the productive forces has a favorable impact on the geographic division of labor and on location of the productive forces, both within each socialist country and in the world socialist system. The economic geography of socialist countries reveals the regularities that determine the rational planned location of production and the formation of territorial-production complexes. Chief among such regularities is the development and location in socialist countries and regions of production facilities in territorial combinations and proportions that will ensure the greatest effectiveness of the economy. Economic geography studies the harmonious combination of specialization and integrated development of economic regions within the framework of a single plan for the development of a country's national economy. The economic geography of socialist countries is characterized by a constructive approach, in which its research findings are used in the practical socialist and communist construction of individual countries and of the whole socialist community (*see* SOCIALIST ECONOMIC INTEGRATION).

In capitalist countries, where the location of production is spontaneous and at cross-purposes, economic geography frequently fails to study concrete socioeconomic conditions and is often used in the interests of capitalist monopolies to justify the location of enterprises in the quest for maximum profits. Some economic-geographical works attempt to offer theoretical substantiation for a geographic division of labor that places industrially developed countries and regions in opposition to backward countries and regions producing agricultural goods and raw materials; the latter countries and regions are exploited by the bourgeoisie of the developed countries. Such a division of labor hinders the development of the productive forces in the less-developed countries.

Marxist-Leninist economic geography scientifically analyzes location of the productive forces and the structural and regional changes in the capitalist countries, and it reveals the contradictions and economic disproportions inherent in the countries' economies.

In the developing countries that are carrying out progressive social reforms, economic geography is afforded the opportunity of helping develop national economic recommendations.

History. References to and descriptions of the economies of individual countries and peoples can be found in works by geographers of antiquity and the Middle Ages. The practical requirements of trade, government, and warfare were important factors in the rise and subsequent development of economic geography. Statistics, as the aggregate of economic and demographic information, later became a data source for the formation of economic geography. In prerevolutionary Russia, elements of economic geography were included in works by statisticians working for *zemstvos* (district and provincial assemblies), in military statistical reports, and elsewhere. The increased geographic division of labor, the strengthening of trade ties, and the formation of a world market created a need to systematize and analyze information on the production of and trade in commodities (the commercial geography of the 19th century). The requirements of the practical administration of government, especially in countries with a vast territory, necessitated scientifically substantiated economic regionalization. In prerevolutionary Russia, economic-geographical research on economic regionalization was conducted by K. I. Arsen'ev, P. P. Ogarev, P. P. Semenov-Tian-Shanskii, D. I. Mendeleev, and V. P. Semenov-Tian-Shanskii.

Owing to the broad development of the geographic division of labor within various countries and in the overall world economy in the era of imperialism, economic-geographical research has

been conducted in most countries, primarily by scholars from the developed capitalist countries. The works produced have been largely descriptive, and in most cases the theoretical substantiations have been apologetic in nature and have contained elements of racism and geopolitics.

As bourgeois economic geography developed, several schools were formed that incorporated various theoretical concepts. The discipline was significantly influenced by the anthropological school, which viewed social (including economic-geographical) phenomena from the standpoint of biological laws (*see* ANTHROPOGEOGRAPHY). The concepts of geographic determinism, environmentalism, and geographic possibilism were widely applied in economic geography. For a long time, bourgeois economic geography developed along the lines of chorological concepts (the German geographer A. Hettner and the American geographer R. Hartshorne), considering as the primary task of geography the study of the unique features and particulars of individual places and thereby actually denying the significance of generalizations and the search for regularities. Great renown was won by the French school of human geography and the cultural landscape school (the German geographer O. Schlüter), whose adherents stressed detailed characterizations of economic-geographical phenomena and the pictorial description of countries. A major contribution to the formation of bourgeois economic geography was made by the works of economists (the German economists J. von Thünen and A. Weber), who promoted the elaboration and introduction of technical and economic methods in economic-geographical research.

The development of the economic sciences was of decisive importance in the formation of economic geography. The laws of social development and geographic division of labor discovered by K. Marx and F. Engels created the basis for formulating a genuinely scientific economic geography. K. Marx' *Das Kapital*, F. Engels' *Anti-Dühring*, and works by V. I. Lenin, such as *The Development of Capitalism in Russia, New Data on the Laws Governing the Development of Capitalism in Agriculture*, and *Imperialism, the Highest Stage of Capitalism*, were of fundamental importance to economic geography.

As a constructive science that actively influenced the territorial structuring of the national economy, economic geography began developing after the Great October Revolution. Socialist construction in the USSR made broad demands on economic-geographical research. A great deal of material was collected in compiling the plan of the State Commission for the Electrification of Russia (GOELRO), in carrying out economic regionalization, and in drafting the first five-year plan. The theoretical principles were based on Lenin's pronouncements in the "Draft Plan of Scientific and Technical Work" and other documents concerning the rational location of production and national policy. Lenin attached much significance to economic geography and included the study of the economic geography of Russia as part of the mandatory minimum for all higher educational institutions (*Poln. sobr. soch.*, 5th ed., vol. 42, p. 427). Especially important in this respect was the research on economic regionalization conducted by the State Planning Commission and the commission of M. I. Kalinin, with the active participation of G. M. Krzhizhanovskii, I. G. Aleksandrov, L. L. Nikitin, and others.

The location of the productive forces of the USSR was discussed at party congresses, during which many concepts of economic geography (such as the basic economic region and the economic nucleus) were introduced into scientific parlance. The resolutions of the Twenty-fifth Congress of the CPSU made provision for a vast program of improvements in the location of productive forces, for development of existing territorial-production complexes and industrial centers and the formation of new ones, for rationalization of transportation and economic ties, and for expansion of scientific research on the location of productive forces (*Materialy 25-go s"ezda KPSS*, Moscow, 1976, pp. 223–24).

A major role was played by N. N. Baranovskii in developing the principles of Marxist-Leninist economic geography in the USSR. In addition to Baranovskii, significant contributions to the consistent development of the methodology and techniques of economic geography were made by N. N. Kolosovskii, V. F. Vasiutin, Ia. G. Feigin, and I. A. Vitver; the concept of economic regionalization was further developed by Kolosovskii, P. M. Alampiev, Iu. G. Saushkin, and V. M. Chetyrkin. In addition to the thorough study of theoretical problems associated with the location of production, important applied studies were made of individual republics, oblasts and raions. Special expeditions were carried out, and economic maps and atlases were prepared and published.

In the development of contemporary economic geography, the postwar period has been characterized by a new upsurge in economic-geographical research. Theoretical problems of economic geography have been elaborated by E. B. Alaev, Baranskii, R. M. Kabo, O. A. Konstantinov, V. V. Pokshishevskii, A. E. Probst, Saushkin, B. N. Semevskii, and others. Applied research in regional geography and the economic geography of branches of the economy has been conducted on a broader front by scholars in the various Union republics.

The formation of a world socialist system has prompted works investigating the economic geography of foreign socialist countries (V. P. Maksakovskii and I. M. Maergoiz). There has been an increase in the proportion of studies devoted to the developed capitalist countries (V. M. Gokhman and S. B. Lavrov) and the developing countries (V. V. Vol'skii and Ia. G. Mashbits), and the geography of the world economy has received more attention (M. B. Vol'f and M. S. Rozin).

New problems have expanded the purview of population geography, determined the rise of natural resources geography (I. V. Komar and A. A. Mints), and intensified interest in general research on the history of economic geography (N. P. Nikitin and Saushkin).

At the same time, ever increasing attention has been devoted to methodology and the search for ways of applying mathematical-economic modeling and other methods in economic-geographical research (M. M. Albegov, M. K. Bandman, N. I. Blazhko, A. G. Grinberg, V. V. Kistanov, and S. A. Nikolaev).

The development of Marxist-Leninist economic geography in socialist countries has been affirmed in the development of a new geography of the national economy that corresponds to the interests of socialist society. Congresses of Communist and workers' parties in socialist countries devote much attention to territorial problems of development of the national economy. Economic geographers have compiled master plans for the future regional location of productive forces.

In the inception and all stages of development of Marxist-Leninist economic geography, a struggle has been waged against the concepts of bourgeois economic geography, which are based on vulgar political economy, philosophical idealism, and geopolitics. Spatial economy, a popular contemporary school in the economic geography of capitalist countries (associated with the German economist A. Lösch and the American economist W. Isard), attempts to resolve the problem of the location of enterprises by using the abstract principle of minimum expenditures of capital, labor, and time without regard for the specific socioeconomic conditions of the regional organization of production. Some economic geographers view economic development processes with respect to regions as the diffusion of innovations, or they may associate the processes solely with poles of growth. Because of its attempts to avoid analysis of the contradictions of capitalism, bourgeois economic geography fails to reveal regularities in economic geography, even though descriptive characterizations contain many concrete data, individual generalizations of some value, and techniques that, if critically applied, can be very useful to the development of economic geography. More and more geographers in the capitalist countries are striving to offer an objective analysis of economic-geographical phenomena.

Methods. Economic geography uses its own methods as well as general scientific research methods. It analyzes statistical data on the location of production, economic relations, and other features of the regions under investigation. It also conducts direct studies of populated areas, enterprises, and microregions (the task force selective study of key specimens) in combination with the complex analysis of statistical data from planning, land management, and other institutions. Research is oriented both toward the individual branches of the economy and toward regional complexes. In the latter case, a special role is played by the economic-geographical synthesis of materials, which makes it possible to reveal the regional unity of elements of a given economic

structure. Important methods include the comparative geographic method, which reveals particulars of the economic development of individual countries and regions, and the cartographic method, which makes it possible to build a unique spatial model, both descriptive and symbolic, of an economic region.

Various types of economic calculations (balance sheets, technical and economic calculations, and the like) and mathematical techniques of quantitative analysis (correlation analysis, mathematical modeling, linear and nonlinear programming techniques, set theory, and the theory of graphs) are used to solve constructive problems involved in justifying the location of production facilities and in comparing proposals for the location of productive forces. They are particularly essential in the study of mass economic-geographical phenomena stemming from an intricate complex of causes and effects. Mathematical economic models are primarily used in the preplanning stage of economic-geographical research and in the solution of problems involving the optimum location of production. The most important mathematical economic models are economic branch models, models of the development of regional complexes, and interbranch and interregional models of the location of the national economy within a country. The optimum location of production is ultimately determined by using a global model, for which local models are only the first stage of development.

Efficiency of production is the criterion used to judge the optimum location of production in a socialist economy. Economic-geographical calculations take into account various economic indexes, in particular, regional differences in the discounted expenditures per unit of output, which depend on the quantity, quality, and location of natural resources, geographic location, transportation conditions, the degree of concentration of production, the technological level of production, specialization, cooperation and combination, the degree of development of a region, and the degree of development of the region's infrastructure. In the formalization of such indexes, it is essential to take into account the specific features of the socioeconomic system of a given country and the regularities characteristic of the given society, that is, whether it is socialist or capitalist.

The qualitative content of economic-geographical phenomena and processes is primarily revealed by conventional methods of analysis, as supported by structural and systems approaches.

The contemporary development of economic geography is characterized by the development of interdisciplinary research on the basic subject. Research may be conducted from various points of view: the ecological aspects of production-related activity, population settlement, and consumption; the sociological and demographic aspects of social reproduction (in their spatial expression); the population's living conditions (this orientation gives economic geography common interests with medical geography and city planning); and evaluation of the resource prerequisites of economic activity. Goal-programming techniques are becoming increasingly important. Such developments expand the framework of economic-geographical research, help make economic geography a self-contained discipline, and integrate the discipline with other geographic and social sciences.

The development of scientific principles for the optimization of the location of socialist production reveals the fruitfulness of the integrated development of countries and regions, which makes it possible to detect "bottlenecks" in individual regions, uneconomical shipment arrangements, and untapped potential in the economy of individual regions.

Scientific research. In the USSR scientific research in economic geography is conducted by the Geographic Institute of the Academy of Sciences of the USSR, the Institute of Geography of Siberia and the Far East, the Institute of Economics and Management of Industrial Production of the Siberian Division of the Academy of Sciences of the USSR, the Geographic Institute of the Pacific Ocean of the Far East Scientific Center of the Academy of Sciences of the USSR, and subdepartments of economic geography of branches of the Academy of Sciences of the USSR; research is also conducted by geographic institutes, departments, and sections of the republic academies of sciences. The location of productive forces is studied by the Council for the Study of the Productive Forces of the State Planning Committee of the USSR, by a number of economic institutes, and by local scientific institutions (for example, by economic institutes attached to the state planning commissions of the Union republics). A great volume of research is conducted at universities—in particular, Moscow University, Leningrad University, the Latvian University, and the universities of Kazan and Tartu—and at other higher educational institutions. The Geographical Society of the Union of Soviet Socialist Republics serves as a public forum for economic geography.

Major centers of economic-geographical research in other socialist countries include economic and geographic institutes of academies of sciences (the Institute of Geography and Spatial Organization of the Polish Academy of Sciences, the Geographical Institute of the Czechoslovak Academy of Sciences, and the universities of Prague and Bratislava), scientific research institutes attached to planning agencies, and subdepartments and departments of economic geography at higher educational institutions.

There has been considerable development in international cooperation in economic geography. Economic geographers of the USSR and other socialist countries participate in various international geographic forums, including international geographic congresses, and in the work of the International Geographical Union and its commissions. At the Twenty-third International Geographic Congress in Moscow (1976), approximately one-half of the papers presented were devoted to economic geography.

Economic geography is primarily a university science in the capitalist countries. Also important are geographic societies and various associations in which there is active interest in the topics of economic geography. Work in economic geography is frequently financed by foundations and capitalist monopolies, and economic geographers work in military, statistical, and other institutions as well as local government agencies and private firms.

The developing countries are faced with the need for economic-geographical research to analyze local natural resources, to ascertain optimum avenues of economic development (especially in the state sector), to effect a rational location of production, and to ensure favorable conditions for participation in the international division of labor. ECONOMIC GROWTH, THEORIES OF, the bourgeois concepts designed to validate the interrelationship and interdependence of the basic categories and rates of expansion of reproduction. Economic growth theories represent the bourgeois alternative to the Marxist theory of reproduction.

Economic growth theories are concerned with (1) the factors that determine potential economic growth, (2) the interdependence of the macroeconomic categories (such as consumption and accumulation) that ensure stable economic growth, and (3) the manner in which stable growth is achieved—that is, whether it is achieved automatically or can only be ensured through state intervention.

The theory of economic growth developed in the 1950's by R. Harrod (Great Britain) and E. Domar (USA) was based on Keynesian premises. In the Keynesian approach to the analysis of economic growth, demand does not automatically equal supply, nor do savings automatically equal investments; demand—especially the demand for capital investment—plays a key role in economic growth; and the basic technological coefficients (for example, the relationship of capital to product, and of labor to capital) remain unchanged because of the rigidity of prices and are determined by the neutral quality of technological progress—that is, by such technological progress as does not influence the effectiveness of production factors.

According to Keynesian models of economic growth, the rate of accumulation is the main strategic factor and the basic parameter of regulation of long-range economic growth. Such growth is stable when savings are a stable proportion of income and capital is in stable relationship to output, creating what is known as a guaranteed rate of growth. Stability, however, is not achieved automatically. Deviations of the actual rates of growth from the guaranteed rate give rise to cyclical fluctuations; deviations of the guaranteed rate of growth from the natural rate (that is, from the rate of growth corresponding to the rate of growth of the population) cause protracted negative trends in the form of economic stagnation or inflation. The maintenance of stable economic growth requires state intervention and the use of tax and budget policies to regulate accumulation and consumption.

Since the late 1950's, the problems of economic growth have engaged the attention of economists of the neoclassical school, including J. Hicks and J. E. Meade in Great Britain and R. Solow and M. Brown in the USA. Their premises were that demand automatically equals supply; that the supply and effective utilization of economic resources play the major role in economic growth; and that the basic technological coefficients are subject to change depending on the prices of production factors and on the nature of technological advances. The chief premise of the neoclassical theory of economic growth was the idea of free competition, with the prices of production factors established at the level of their marginal products, thus supposedly ensuring a stable economic equilibrium.

On the basis of these assumptions, the economists of the neoclassical school proposed their own model of economic growth. The Cobb-Douglas production function was such a model; together with more complex production functions, it was the basis of a system of indicators that showed the dependence between expenditures and production output (coefficients of the elasticity of output based on resources) as well as the interdependence of the expenditures themselves (maximum rate and elasticity of replacement of resources). A system of quantitative characteristics was devised to show the economic influence of technological progress—such progress being either neutral or not (that is, influencing the effectiveness of production factors), and either materialized (that is, embodied in the means of production) or nonmaterialized (that is, not embodied in the means of production).

Empirical evaluations of the parameters of the production function play an important role in the analysis of the quantitative interrelationships that determine maximum potential output. Specifically, these evaluations were a basis for the conclusion that the main strategic factors of long-term economic growth were technological progress and its determinants—namely, improvements in the quality of equipment, in the level of skills of the work force, and in the organization of production. The economists of the neoclassical school, however, did not use the production function simply to arrive at empirical evaluations; they used it instead as a suitable mathematical form for interpreting the problems of dynamic economic equilibrium on the basis of the vulgar apologetic premises of neoclassical theory. The neoclassical theory of economic growth is designed to prove that the capitalist economic system is internally stable and possesses the necessary mechanisms for automatic restoration in the event of disturbance of the equilibrium. According to this school of thought, state intervention in the economy must be reduced to a minimum and be confined primarily to monetary and credit policies.

The neoclassical theory of economic growth also provides an explanation of the mechanics of distribution of national income. According to the theory, each production factor (that is, labor and capital) receives a share of the output corresponding to its own proportion and marginal productivity. Any change in this share is supposedly due solely to the influence of "nonneutral" technological progress. This theory of growth is thus aimed at distorting and concealing the genuine relations of production and distribution under capitalism.

Both Keynesian and neoclassical theories of economic growth are currently in a state of profound crisis, which results from their failure to conform to reality given the increasingly pronounced contradictions of capitalism. The methodological principles of these theories are the object of heated criticism even within the framework of their own bourgeois political economy.

ECONOMIC INCENTIVE, a system of measures that uses material means to motivate participants in production to work for the creation of the social product. The nature, form, and methods of economic incentive depend on the dominant production relations of a society.

Under capitalism, economic incentive is contradictory in nature. The actions of owners of the means of production—capitalists—are inspired by the possibility of appropriating surplus value through the exploitation of hired labor. Economic necessity is the labor motivation of industrial workers and all the toiling masses who are deprived of the means of production (*see* CAPITALISM).

Under socialism, economic incentive is based on the law of distribution according to labor. It is determined by the dominance of socialist production relations, which exclude the exploitation of one person by another, since all participants in production are simultaneously the owners of the means of production and of their own labor power. Under such conditions, the unity of three types of interests is achieved—societal, collective, and personal. The most important principle of economic incentive states that "what is good for society must be good for each production collective and each worker."

Economic incentive in socialist production is ensured by the existing system of management (*see* PLANNING, NATIONAL ECONOMIC). Profit-and-loss accounting (economic accountability) and the use of such key economic levers as profit, price, and credit play a major role in economic incentive in socialist enterprises.

Incentive funds (including the fund for the expansion of production, the material incentive fund, and the social-cultural and housing fund) are created at enterprises according to the overall quantitative and qualitative results of the economic activity of a given enterprise collective (such as the growth of labor productivity, reduction of the prime cost of production, increased profitability, and improvement of product quality).

Economic incentive for workers in both state enterprises and kolkhoz and cooperative enterprises depends in large measure on the organization of the wages of industrial and nonindustrial workers and on the remuneration of the labor of kolkhoz workers—the basic form of distribution of the necessary product and the most important means of offering personal material incentive under socialism (*see* WAGES).

One of the most important trends affecting economic incentive is the improvement of the economic mechanism and of economic incentive itself. Such improvement is realized in the stage of developed socialism, given the concurrent strengthening of democratic centralism in economic management.

In addition to material incentive and responsibility under socialism, moral incentive also plays an increasingly important part in economic incentive (*see* MATERIAL AND MORAL STIMULATION).

E. L. MANEVICH [29–1883–1]

ECONOMIC INFORMATION, information about economic relations and the processes of social reproduction; the information is used in the system of management of the national economy alongside other types of information, such as technical information that reflects the interrelationships among the physical elements of production. From the standpoint of persons receiving the reports and data, economic information is valuable only to the extent that it is new and useful for solving some problems in the national economy.

Economic information may be classified by content as follows: (1) by phases and processes of reproduction—information on production, distribution, exchange, and consumption; (2) by elements (or factors) of reproduction—information on population and labor resources, natural resources, output and services, monetary capital, and the like; and (3) by the structural units represented—sectors of the national economy, economic regions, enterprises and organizations, and so forth. From another point of view, it is important to classify economic information by its affiliation with a particular management function: planning economic information, which is developed during the planning process; accounting and statistical data, which arise from the functions of accounting and analysis; normative economic information; parity-check data; forecast data; and other types.

Economic information may be classified as background or management information depending on its effect on the user. Background information contains facts used in substantiating decisions. Management information contains the results of decisions that have been made and are being conveyed to others to be carried out. Management information may be presented in the form of direct assignments or as economic and other types of incentive that affect the behavior or functioning of the objects of management.

Directed and undirected economic information are distinguished by the method of delivery to users. Directed information is presented to one or several specific addressees, usually in standardized document form on a uniform time schedule. Undirected economic information has general application, and users will usually search it out themselves when the need arises.

Economic information is transmitted and processed in the form of symbols recorded on various carriers. The symbol systems used to represent economic information constitute economic information languages. Natural language is their common basis, but in economic management a vocabulary and standardized forms of expression have been developed that are specific to the economic information languages; this has occurred mainly in connection with the widespread use of standard tabular documents in flows of economic information. The use of computer technology to process economic information promotes the spread of various types of artificial languages: classifier-type languages, descriptor-type information languages, and others. The USSR is developing and introducing the Uniform System of Classification and Coding of Technical and Economic Information (ESKK TEI). Its purpose is to ensure uniform (within the country), unambiguous, and formalized representation of the elements of economic information. By 1977, 20 all-Union classifiers and systems of designations had been formulated and ratified as part of the ESKK. They included classifiers for branches of the national economy; industrial, agricultural, and construction output; minerals; work and services in various sectors; enterprises and organizations; and units of measure. Work began in the mid-1970's on an all-Union classifier of technical and economic indicators (OKTEP), which will have a central place in the ESKK. It will create the prerequisites for the ESKK to develop in the direction of formulating compatible information languages to describe economic information with the wide use of computers. In addition to the ESKK, a set of standardized document systems is being devised, to include accounting, report, planning, design, production-engineering, and other documents.

The indicator (index) is the typical form of expression of quantitative data for economic information. It may be a variable that characterizes one of the properties of the economic object depicted or a quantitative value for the variable. Qualitatively, an indicator is defined by a set of significant features; quantitatively, it is determined by measurement or calculation. Indicators of economic information may be consolidated into a system by es-

tablishing various relationships among them. The system forms the methodological foundation of the overall system of collecting and processing economic information and ensures that all quantitative data can be combined and compared.

The functions performed by different management bodies within the system of national economic management are joined by flows of economic information. In turn, such flows reflect the entire functional and organizational structure of management. Flows of economic information may be described in terms of direction, composition, intensity, and time. With respect to direction, there are horizontal flows (connecting management bodies at the same level) and vertical flows (ascending and descending, connecting management bodies at different levels). The composition of information flows is determined by the content of the messages transmitted. The intensity is defined by the volume of data transmitted per unit of time. With respect to time, economic information may be periodic (daily, monthly, annual, and the like) or nonperiodic (occasional or when deviations occur).

The bulk of economic information in circulation is made up of primary and bookkeeping data (within enterprises), transportation and payment-charge documents (in circulation between enterprises), bookkeeping and statistical reports, planning and normative documents, and operational management information. According to the findings of various studies, the annual internal circulation of recorded economic data within an industrial enterprise is from 50,000 to 2 million documents (from 3.5 million to 100 million indicators). The external circulation (volume of input and output data) of an industrial enterprise is approximately 100,000 documents and 1 million indicators per year. Of this, transportation and payment-charge documents account for 80–90 percent of the documents and 40–50 percent of the indicators. An industrial enterprise submits an average of 60,000–80,000 indicators per year in statistical and bookkeeping reports. The largest processing center for economic information is the network of institutions of the State Bank of the USSR (Gosbank), which manages more than 1 million accounts for 570,000 enterprises and organizations, concentrating information on all primary processes of production, distribution, and circulation of the social product. The principal methodological and organizational center for accounting and statistical economic information is the Central Statistical Board under the Council of Ministers of the USSR.

The chief lines of development of the current system of economic information stem from the challenge of improving the management of the national economy and putting it on a new technical basis. The growing complexity of management functions demands greater thoroughness, timeliness, and reliability of economic information; the introduction of modern computers, communications equipment, and the like creates the necessary preconditions for meeting such demands. Qualitative changes in the system of economic information are linked with the sequential development (following the decisions of the Twenty-fourth and Twenty-fifth congresses of the CPSU) of the all-Union system for the collection and processing of information for accounting, planning, and management. The system of economic information is being integrated by stages on a new technical basis. It will provide comprehensive use of an essential minimum of collected data and the maximum possible extraction of information from such data to solve the multifaceted problems of management.

ECONOMIC LAWS, the necessary, stable, and recurrent causal relationships and interdependences of economic phenomena in the course of the production, distribution, and exchange of goods and services at various stages of development of human society. Economic laws reflect the most essential and typical features of the operation and development of a given system of production relations. Every economic law expresses the unity of the qualitative as well as quantitative aspects of economic phenomena and processes and serves as an internal measure of these processes.

Economic laws, like natural laws, are objective. Unlike natural laws, however, they operate and manifest themselves only through the concrete labor and productive activity of society's members. "Men make their own history, but they do not make it just as they please; they do not make it under circumstances chosen by themselves, but under circumstances directly encountered, given, and transmitted from the past" (K. Marx, in K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 8, p. 119). People are not free in their choice of productive forces and material living conditions. Preceding generations develop the productive forces in the process of their labor activity and leave them to succeeding generations. This bond in human history ensures the objective nature of economic development, which is ultimately independent of the will and consciousness both of individuals and of society as a whole.

Economic laws are historical in nature. Their content, mode of action, and forms of manifestation depend on the level of development of the productive forces. People enter into historically determined mutual economic relationships, and their activity is found to be subject to various economic laws. History knows five modes of production, based respectively on the primitive communal system, slavery, feudalism, capitalism, and communism (with socialism as its initial phase). Each mode of production has its own inherent system of economic laws.

The nature of economic laws and the manner in which they are manifested are directly dependent on the type of ownership of the means of production, on the level of actual socialization of production, and on the nature of the economic bonds between the parties in production relationships. In all antagonistic socioeconomic formations, economic laws operate spontaneously and are manifested as an external blind force that compels people to act in a given way.

Under capitalism, given the anarchy of social production arising from the contradiction between the social character of production and private capitalist appropriation, the internal laws of social reproduction manifest themselves in the objective form of economic crises of overproduction; these crises periodically shake the economy of bourgeois society, thereby ensuring "a *constantly disturbed* proportion" in the economy's development (V. I. Lenin, *Poln. sobr. soch.*, vol. 3, p. 621).

In socialist society, competition is replaced by relations of comradely cooperation and mutual aid. The supremacy of public ownership and the planned organization of the entire national economy make it possible to take into account all aspects of the economic laws and to consciously implement them at all levels of socialist management.

Economic laws differ in content and in effective duration. *General* economic laws are characteristic of all socioeconomic formations. This category includes the law of the correspondence of production relations to the nature and level of development of productive forces, the law of the increasing productivity of social labor, and the law of economy of time. At each stage of historical development these laws assume different forms and produce different economic effects. Thus, at the time when the mode of production of the primitive communal system shifted to the mode of production based on slavery, the law of the correspondence of production relations to the nature and level of development of productive forces had the effect of eliminating primitive communal ownership and of establishing and consolidating private slaveholders' ownership of slaves and of the material means of production.

In the transition from capitalism to socialism, the same law operates to eliminate private capitalist ownership of the means of production (and ultimately to eliminate all forms of private ownership of the means of production) and to consolidate public ownership of the means of production in its two forms: (1) public, or state, ownership of the decisive means of production and (2) cooperative ownership of the major portion of the means of agricultural production.

Other types of economic laws are operative only in some, rather than in all, socioeconomic formations—namely, where there is commodity production. This category includes the law of value, the law of money circulation, and the law of supply and de-

mand. The law of value was already functioning at the time when the primitive communal system began to disintegrate—that is, after the first major divisions of labor in society (the separation of cattle raising from farming, and of handicrafts from agriculture). The law of value was limited in its range of operation under the mode of production of the slaveholding system and subsequently under the feudal mode of production; it operated most extensively under the capitalist mode of production, and it is still in effect, expressing a different social content of economic relations in the period of transition from capitalism to socialism and under socialism. The law of value will ultimately die out in the second phase of the communist socioeconomic formation—namely, when full communism has been achieved.

Specific economic laws, which make up a distinct category, operate only under a specific mode of production. They reflect the significant features in the operation and development of historically determined production relations. Specific economic laws are precisely the laws that make principled distinctions between different systems of economic laws. Certain specific economic laws operate only in certain phases or stages of a given mode of production. Thus the system of economic laws of monopoly capitalism has certain new features that distinguish it from the system of economic laws of premonopoly capitalism (for example, the law of monopoly profit under imperialism). The system of economic laws of the socialist phase is gradually transformed into the system of economic laws of full communism, which is communism's second and highest phase. For example, the law of distribution according to labor will be gradually transformed into the law of distribution according to needs.

The primary objects of study of political economy are the specific economic laws that most fully express the socioeconomic nature and historically determined place of one or another system of production relations. Political economy "must first investigate the special laws of each individual stage in the evolution of production and exchange, and only when it has completed this investigation will it be able to establish the few quite general laws which hold good for production and exchange in general" (F. Engels, in K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 20, p. 151).

The emergence and increasingly greater effect of specific economic laws go hand in hand with the establishment and development of historically determined production relations in unity with productive forces. The system of economic laws of a given mode of production represents the integral system of necessary and substantive internal relationships and dependences of that mode of production that characterizes as fully as possible its essence and direction of development. This system includes the basic economic law of a given mode of production, determining the specific goal of social production and the appropriate means to attain that goal; the economic law of the appropriation of the necessary and surplus product by various classes and social groups; the economic law that reflects the specific distribution of social labor and means of production among various branches of production and types of activity; the economic laws of reproduction, which demonstrate the correlation between production of the means of production and production of consumer goods, or between the first and second subdivisions of social production, as well as within each of these subdivisions; the economic laws that characterize the distribution of consumer goods among direct producers; the economic laws that express the essence of secondary, or transferred, production relations, such as international economic relations; the economic laws of individual spheres of social production; and the general economic laws operating under the conditions of a given mode of production.

The knowledge and utilization of economic laws are two reciprocally determined aspects of society's mastery of the laws governing the functioning and development of the economic system. People are able to master economic laws—that is, to comprehend them, to use them in a certain way, and to direct the law's effect toward the satisfaction of their economic interests. The knowledge and utilization of economic laws in an antagonistic society are class-oriented, serving the interests of the classes that own the means of production. The exploitative essence of capitalism and the spontaneous nature of capitalist economic development exclude the possibility of well-planned organized actions on the part of the masses with the aim of deliberate utilization of economic laws. Under socialism, economic laws are comprehended and utilized by the working class in the interests of society, and under advanced socialism, by all the people under the leadership of the working class.

Some elements of objective analysis of the economic laws of capitalism can be found in the works of such classical bourgeois political economists as W. Petty, F. Quesnay, A. Smith, and D. Ricardo.

K. Marx and F. Engels, the founders of the theory of scientific communism, examined the capitalist system of economic laws and revealed the objective inevitability of the downfall of capitalism, showing that the proletariat is destined to dig its grave. V. I. Lenin brought to light the distinctive effects of the economic laws of capitalism under the rule of the monopolies, defining imperialism as the highest and last stage of capitalism. He proved that uneven economic and political development is an unconditional law of capitalism. In the age of imperialism, the victory of the proletarian revolution may initially come in a few countries only, or even in a single country. Socialist revolution expresses the conscious utilization by the masses, under the leadership of the proletariat, of the law of the correspondence of production relations to the nature and level of development of productive forces, thereby ushering in the age of socialism and communism in which the spontaneous action of economic laws is replaced by their purposeful utilization in the interests of society.

Knowledge of economic laws includes discovery of the internal content, general direction, quantitative determinability, and immanent forms of manifestation of each law and consequent discovery of the significance of a given law in the context of economic development; study of the material prerequisites and economic conditions that are the basis of the laws' operation and interaction in the system of economic laws; identification of the specific forms in which a law manifests itself under specific socioeconomic conditions and depending on the scale of the object under study (a single enterprise, an economic region, branch, or sphere, the national economy as a whole, or the world economy); elucidation of the requirements of a given economic law both in general terms and with respect to specific historical conditions; and finally identification of those objective trends in economic development that lead to the extinction or modification of a given economic law.

It is only under socialism and communism that the use (preceded by knowledge) of economic laws in the interests of society is both possible and necessary, this being the main form of implementation of such laws; it is only under socialism and communism that the direct producers are united by the social nature of production and public ownership of the means of production.

The scientific principles underlying the utilization of economic laws under socialism were set down in the works of K. Marx, F. Engels, and V. I. Lenin; they are elaborated and developed in the documents of the CPSU and other communist and workers' parties and in the works of Marxist scholars. The utilization of economic laws is effected by means of the economic policies of communist and workers' parties and socialist states. Economic policies are concretely implemented in the various types of economic and organizational activities of the state. Such activities include the planned management of the socialist economy (economic forecasting, planning, organization, and management, the provision of performance incentives, and accounting and monitoring of production and distribution), as well as the broad dissemination of economic knowledge among all working people and the training of personnel for the national economy.

The effective utilization of economic laws presupposes in-depth and comprehensive analysis of the state of the economy and of the objective trends of its development at a given stage; elaboration of a scientifically valid notion of the desired results of economic development, commensurate to society's resources and potential as well as to its developing needs; and determination of the specific effect of various social forces and possible ways of combining them toward the attainment of contemplated results in accordance with the requirements of the system of economic laws. All this constitutes the economic strategy of the communist and workers' parties and socialist states. The elaboration and implementation of economic policies also include such economic

tactics as the continuation and concretization of economic strategy. Economic tactics are the actual techniques and means by which economic policies are applied to individual branches of the national economy, to individual economic regions, and to workers' individual social groups over a relatively short time.

The manner and extent of the economic laws' utilization serve at the same time to test the truth of the theoretical knowledge that has been obtained on the system of economic laws, and they are a most important condition for thorough knowledge of such laws.

ECONOMIC MANAGEMENT, a concrete historical method of influencing the process of social labor in accordance with the objective laws of social development; one of the principal forms of social control. Economic management involves both the production and the nonproduction sphere (*see* ADMINISTRATION AND MANAGEMENT). [29–1884–1]

ECONOMIC MAPS, topical maps that illustrate various economic phenomena and activities.

A distinction is made between general economic maps, which describe the economy as a whole (including maps of economic regions, territorial-production complexes, economic centers, economic ties, levels of economic development, and specialization of production), and maps of various branches of production and spheres of circulation (including industry maps, agricultural maps, transportation and communications maps, and maps of the construction industry and trade and finances). Maps depicting labor resources and natural resources as components of economic activity are also classified as economic maps. Resource evaluation maps (depicting agroclimatological resources, conditions of economic development of regions, conservation, and the like) are classified midway between economic maps and maps of the natural world.

The first hand-drawn economic maps in Russia appeared in the late 17th century; printed maps were first published in the 1840's. The most important economic maps compiled before the October Revolution were made after the reforms of the 1860's, for example, the *Statistical Atlas of the Principal Sectors of Factory Industry in European Russia* (1869–73) and *Trade and Industry Map of European Russia* (1900), compiled by V. P. Semenov-Tian-Shanskii.

Economic maps are used to facilitate planning and forecasting the development and location of productive forces as well as for management of the national economy. The first widely known Soviet economic map was the *Schematic Map of the Electrification of Russia* (1921), compiled at the initiative of V. I. Lenin. Compilation of the *Great Soviet Atlas of the World* (1937) and of the economic and comprehensive atlases of the USSR and individual regions of the country represented a significant contribution to domestic and world economic cartography. Further achievements in the postwar years have included a series of economic atlases of the USSR and other countries, comprehensive atlases of the Union republics, krais, and oblasts, and economic maps for reference, education, and agitation and propaganda.

ECONOMIC MATERIALISM (also economic determinism), the dogmatic simplification of the materialist interpretation of history. In essence, economic materialism reduces the wealth of the dialectics of social development to the operation of a predominant age-old "economic factor." While recognizing economics as the subject of history, economic materialism views people as the passive "element" of the productive forces or as the products of production relations. From the productive forces and production relations, economic materialism schematically deduces all other phenomena of social life that have no active role of their own. Economic materialism views people solely as personifiers of economic categories, or economic personae.

The ultimate expression of economic materialism can be found in the vulgar sociologism of V. M. Shuliatikov. Economic materialism as a whole is characteristic of the opportunist "tradition" (of E. Bernstein, for example). It is also manifested in the works of certain Marxists, such as A. Labriola, P. Lafargue, and F. Mehring. As V. I. Lenin pointed out, what led to the emergence of economic materialism was the assimilation of Marxism "in an extremely one-sided and mutilated fashion [by those who] had learnt by rote certain 'slogans,' certain answers . . . *without having understood* the Marxist criteria for these answers" (*Poln. sobr. soch.*, 5th ed., vol. 20, p. 88). Criticism of economic materialism is a necessary condition of the creative development of Marxism.

ECONOMIC MODEL, MATHEMATICAL, a model of an economic entity or process the description of which involves the use of mathematics.

Mathematical economic models may be constructed to analyze various premises and principles of an economic theory, to provide logical substantiation of observed economic patterns, or to process and systematize empirical data. Their applications include the practical forecasting, planning, and management of the national economy and the improvement of planning and management of the economic mechanism as a whole and of other aspects of society's economic activity.

According to their purpose, models may be classified as descriptive and constructive. Descriptive models are used to help explain various existing economic phenomena and processes.

Classic examples are models of economic growth and models of competitive economic equilibrium. The latter may be regarded as the first mathematical economic models in history. Their origins can be traced back to the famous *Economic Table* of the Physiocrat F. Quesnay. In this work Quesnay attempted to explain the creation and redistribution of income.

Modern equilibrium models involve aggregates of producers and consumers, the producers being described by means of a set of production capabilities and the consumers being described by means of certain functions or procedures that specify a preference or a choice of consumer goods. Producers try to select a mode of production that will produce maximum profit, and consumers seek to obtain the market basket of goods that will bring them the maximum degree of satisfaction for the money they have to spend. The consumers' funds (budget) are formed from producers' profits through some specified profit redistribution mechanism. A state of equilibrium is attained when no producer or consumer is interested in altering his activity. Equilibrium models are used for the description of both capitalist and socialist economies. In essence, the coordination of various, including opposing, interests is investigated in such models.

Descriptive models include economic growth models designed to forecast the basic aggregate indicators of development of the national economy and forecasting models for various parts of the economy. The latter models, which are based on mathematical statistics, particularly on correlation analysis, are used to study and forecast the behavior of multifactor economic processes, such as the dynamics of prices on the world market or of stock exchange indexes. Also classed as descriptive models are models that merely simulate the behavior of various parts of the economy, for example, models that simulate the development of an enterprise or firm.

The development of constructive models represents a new stage in the modeling of economic phenomena. The principal distinctive feature of such models is that they model the economy that society creates; in particular, they model desirable changes in the existing economy. Constructive models have had a considerable influence on the development of economic theory as a whole. The first models of this type were the reproduction schemata of K. Marx, the analysis of which led Marx and subsequently V. I. Lenin to conclude that the production of means of production—especially the production of means of production for the production of means of production—necessarily develops more rapidly than does the production of consumer goods (*see* REPRODUCTION).

The constructive approach to the modeling of economic phenomena is inherent in the socialist economy, in which economic construction can be carried out on a scientific foundation. The discovery of linear programming, a mathematical discipline for analyzing and solving extremum problems with constraints, in the late 1930's stimulated the rapid development of constructive models. The optimal planning model of a socialist economy was developed on the basis of linear programming. Within the framework of this model precise definitions were obtained of such concepts as optimum, optimal plan (*see* OPTIMUM, NATIONAL ECONOMIC), social utility, and socially necessary expenditures of labor. This model, like the model of an ideal gas in physics, was an ideal model; it generated an entire spectrum of optimal planning models that take into more complete account various aspects of the actual planning process. To be sure, the model incorporated such assumptions as the linear dependence of output on expenditures, the infinite divisibility of products, the existence of an exact mathematical formulation of the global objective of society, the absolute admissibility and validity of the information used, and the presence of infinite computational capacity. Nevertheless, it provided the foundation for the theory underlying the System for the Optimal Functioning of a Socialist Economy (SOFE), which is being developed in the USSR.

In terms of their basic premises, optimal economic growth models may be classed as optimal planning models. They are used to investigate the potential development of an economic system over time and to define the optimum of economic growth and the factors that influence the maximum growth rate.

The further development of planning models necessitates the creation of systems of planning models where each model in a system is developed and used by an appropriate planning or administrative agency. Mathematical means are being developed for the purpose of resolving problems relating to the coordination of the solutions of individual models. As economic factors are incorporated into models with increasing precision, the models become more complicated, and their subsequent analysis and, in some measure, use become more difficult. For this reason, computers have been increasingly used in the construction, analysis, and practical application of models.

The division of mathematical economic models into descriptive and constructive types is somewhat arbitrary. For example, the report intersector balance is a purely descriptive model, but the planning intersector balance has both descriptive and constructive properties. The construction of integrated models of the functioning of economic systems is one of the basic trends in the development of mathematical economic models. The models of functioning reflect not some isolated economic process, such as the planning process, but the aggregate of all basic processes, including planning, production activity proper, material and technical supply, management of plan fulfillment, coordination of the interests of different agencies, and pricing. For this reason, the model of the functioning of an economic entity consists of building blocks that use diverse mathematical apparatus. The analysis of such an integrated model involves primarily numerical experiments using computers and appropriate statistical processing.

The variables that are to be defined as a result of the "solution of the model" may be not only numerical characteristics, such as output volume or the use or nonuse of various technological methods, but also the algorithm of activity or the structure of the interaction of parts. For example, algorithms pertaining to the compilation of the plan vary, as do algorithms relating to the interaction of enterprises and of material and technical supply agencies; in addition, the production structure of enterprises varies.

ECONOMIC PATTERN, a type of social pattern (*see* CONFORMITY TO LAWS OF SOCIETY). Economic patterns are usually the aggregate result, or resultant, of several economic laws acting simultaneously. The relations and dependencies reflected in economic patterns are therefore more complex and multivariate than the relations and dependences reflected in economic laws.

[29–1849–1]

ECONOMIC POLICY, the system of economic measures implemented by the state in the interests of the dominant class in presocialist formations or, under socialism, in the interests of all society; a branch of economic science.

The social content and objectives of economic policy and the means chosen to achieve its goals are determined by the character of the social system and ownership of the means of production. Like all policies, economic policies are the concentrated expression of economics, or of historically determined modes of production. The economic policy of the political party in power is influenced by numerous factors, such as the relationship between class forces, the stage of development of the class struggle in a given country and in the international arena, and the state of peace or war.

Economic policy dates back to the inception of classes and the formation of the state. In a society with antagonistic classes, it reflects the interests of the exploiting classes and is the means by which such interests are protected and realized. Under slavery and feudalism, economic policy was generally confined to the imposition of taxes and the regulation of monetary circulation. In the formative period of the capitalist mode of production, the bourgeois state took measures to establish and develop manufacturing enterprises and adopted laws that consolidated the supremacy of capital over hired labor; mercantilism and protectionism became widespread.

The growth of the industrial bourgeoisie gave rise to the policies of free enterprise and free trade. The economic policy of the bourgeois state during this period reflected the historical conditions of free-competition capitalism. In the age of imperialism, the bourgeois state has increasingly intervened in the process of capitalist reproduction. State monopoly regulation is a complex mechanism of socioeconomic and political maneuvering that is used to preserve the capitalist economy. It includes such measures as economic programming, development of the state sector, subsidies, anti-inflationary measures, and credit and financial activities directed toward foreign economic expansion (for example, tax advantages for export monopolies, government-guaranteed exports, and customs policies).

To a considerable degree, the capitalist countries' monopolies use the machinery of the state for their international operations. The period that followed World War II saw the emergence and growing range of activities of international monopoly organizations—some encompassing a particular branch in its entirety, such as the European Coal and Steel Community, and some designed for a more general type of economic integration, such as the European Economic Community.

In the age of imperialism, the economic policies of the bourgeois states and parties reflect capitalism's adaptation to new historical conditions. Such policies, however, cannot ensure the planned development of the economy on the scale of the entire society or the stabilization of capitalism as a system. The general crisis of capitalism continues to mount. The economic policy of the bourgeois states as a whole, being diametrically opposed to the fundamental interests of the working people, leads to even sharper class contradictions.

In the developing countries that pursue an independent course, economic policy is aimed at limiting the omnipotence of the foreign monopolies, establishing a state sector in the economy, developing industrial production, and implementing agricultural reforms. These countries favor the establishment of a new international economic order with just and equitable international division of labor and foreign economic exchange.

Economic policy plays a fundamentally different role under socialism—a system that is based on the public ownership of the means of production and that develops according to plan through the conscious use of economic laws. Through its economic policies, the socialist state regulates material production—the basis of society's development—and in so doing determines the future prospects and tempo of social progress, directly influences changes in the social structure and the people's greater well-being, and ensures the solution of the basic socioeconomic problems of communist construction. Through their successful efforts to build communism, the socialist countries exert a decisive influence on world development.

Fundamental economic policy, economic strategy, and current economic targets are determined by the communist and workers' parties of the socialist countries—primarily at the party congresses and at the plenary sessions of the leading central party organs. The economic policy of the communist parties, which is based on Marxist-Leninist theory, expresses the fundamental interests of the toiling masses headed by the working class and of all strata and social groups in socialist society; it is distinguished by its scientific character, realism, goal-directedness, and consistency.

V. I. Lenin formulated the most important principles of the economic policy of the socialist state. The basic tenets of economic policy are concretized and implemented in the activity of the socialist state through the national economic system of management and planning. The state's long-term, or five-year, and one-year plans reflect the conditions and specific characteristics of a given period of the country's development. Under the specific conditions that evolved in the first few years after the victory of the Great October Socialist Revolution in Russia, the Communist Party and the Soviet state implemented the policy of "war communism" and the New Economic Policy. Industrialization, the collectivization of agriculture, and the cultural revolution created a mighty industry and overcame the country's age-old backwardness, thus ensuring the victory of socialism.

Starting with the late 1930's, the economic policy of the CPSU and of the Soviet state was aimed at strengthening victorious socialism, building an advanced socialist society, expanding and consolidating the material and technical basis for socialism, developing socialist production relations, and raising the living standard and cultural level of the working people. Until the mid-1950's, the major portion of the country's accumulation fund was used to accelerate the rate of development of heavy industry—an effort dictated by the need to restore the national economy, which had been destroyed during the Great Patriotic War of the Soviet Union of 1941–45, and to strengthen the economic and defensive power of the Soviet nation and of the entire world socialist system. After the mid-1950's, the Soviet state was able to allocate a greater part of its resources to the development of light industry, housing construction, and agriculture. By the late 1950's, the material and technical basis for socialism had been strengthened and the USSR was a mighty and invincible power. Socialism was finally and totally triumphant.

The building of an advanced socialist society in the USSR was contingent on the development of long-range economic policies and economic strategy under new conditions. With the general upsurge of the economy, it was found that the existing planning techniques and economic production incentives were not appropriate to the higher level reached by the productive forces and were indeed hindering the latter's development. Therefore in the 1960's and 1970's the party and the state concentrated on basic improvements in production relations, in the management of the national economy, and in the planning and stimulation of production. These objectives were reflected in the documents of the March (1965) and July (1970) plenums of the Central Committee of the CPSU (CC CPSU) on the development of agricultural production; in the decree of the CC CPSU and Council of Ministers of the USSR (1966) introducing a guaranteed monthly wage for kolkhozniks; in the decisions of the September (1965) plenum of the CC CPSU on improved planning and stronger economic incentives for industrial production; and in the decree of the CC CPSU and the Council of Ministers of the USSR (1973) on the further improvement of industrial management.

An economic strategy corresponding to the conditions and tasks of advanced, or mature, socialism was devised by the Twenty-fourth and Twenty-fifth Congresses of the CPSU. "Like any other strategy, the party's economic strategy begins with the formulation of tasks, with the articulation of fundamental, long-term goals. . . . Economic strategy also includes a precise determination of the ways and means to attain these goals" (*Materialy XXV s"ezda KPSS*, pp. 39, 40). The October (1976) plenum of the CC CPSU, which approved the tenth five-year plan, defined the key issues of economic development and devised a set of effective tactics for the solution of economic and political problems.

The supreme goal of the economic policy of the socialist state and of the party is the steady rise of the living standard and cultural level of the population. The system of advanced socialism offers greater opportunities to realize this goal, making it possible to more fully satisfy the people's growing material and nonmaterial needs, to improve the socioeconomic and production conditions of labor, to raise the level of the socialist mode of life, to perfect the structure of Soviet society, and to reduce the differences in affluence, cultural level, and working and living conditions of the different social groups in the cities and rural areas. The long-range goals of economic policy are set forth in concrete terms in the social program of the five-year plans (for example, the program for social development and for raising the people's standard of living in the tenth five-year plan, established by the Twenty-fifth Congress of the CPSU).

The principal means employed to achieve the stated goals are (1) increasing the effectiveness of social production through its intensification, (2) accelerating the rate of scientific and technological progress, (3) raising labor productivity and improving the quality of all types of work throughout the national economy, and (4) coupling the attainments of the scientific and technological revolution with the advantages of socialism. The policy of increasing the effectiveness of social production is occasioned both by the long-term task of establishing the material and technical basis for communism and achieving victory in the economic competition with the capitalist system and by the specific conditions of the national economy at the present stage of development—in

particular, by the limited possibility of expanding production at the expense of nonintensive factors.

The party's economic strategy determines the basic directions in the development and improvement of production at any given stage. Thus the tenth five-year plan (1976–80) posed the task of promoting further growth in the country's economic capacity, expanding and radically renewing the social funds, and securing the stable and balanced growth of heavy industry, which is the economy's foundation. These tasks can be successfully accomplished by implementing the uniform scientific and technological policy that is a basic component of the party's and the socialist state's economic policy.

Economic policy includes capital investment policy and the rational allocation of productive forces, income, prices, and wages, as well as agricultural policy, financial and credit policy, and demographic policy. The policy of rational utilization of natural resources and environmental protection is increasingly assuming a separate identity. Foreign economic policy is an important part of economic policy; it contributes to socialist economic integration, the strengthening of stable and mutually advantageous cooperation with the developing countries, and the expansion of economic, scientific, and technological relations with the industrially developed capitalist countries based on the consistent observance of the principles of peaceful coexistence.

The successful implementation of the economic policy devised by the Marxist-Leninist parties of member nations of the Council for Mutual Economic Assistance enabled the majority of these countries to complete the transition from capitalism to socialism and to build a socialist society. The economic policy of these countries is now aimed at securing the further growth of social production, increasing its effectiveness, and raising the people's material and cultural standard of living. Current efforts are devoted to building the advanced socialist society.

Socialist economic policy is distinguished by its humanistic objectives and its genuinely popular character. The constantly expanding participation of the working people in the formulation and implementation of economic policy is an important ruling principle of socialist and communist construction. Such participation takes various forms—namely, the nationwide discussion of key documents pertaining to economic policy, the workers' participation in the solution of problems related to production and in the work of various social organizations, and the wide-ranging extent of socialist competition.

Economic policy is taking shape as an increasingly important and independent scientific school that investigates the scientific foundations and principles of political direction of the economy and explores the practical implementation of economic policies at various stages of development of socialist society. Economic policy is based on Marxist-Leninist philosophy and political economy and on the theory of scientific communism; it also takes into account the achievements of allied sciences—for example, theories of planning and management, sociology, and law. In the course of formulation of economic strategy and tactics, recommendations are made for improved management of the national economy, and ways and means are determined to mobilize the working masses for resolution of the problems confronting society. Many of the questions that fall within the scope of economic policy as a branch of science are open to debate—for example, the question of defining the subject matter and distinctive methods of economic policy that differentiate it from allied scientific disciplines. In the USSR the program of the political and economic education system includes the study of the economic policy of the CPSU.

L. I. ABALKIN [29–1828–3]

ECONOMIC POTENTIAL, the aggregate capacity of branches of the national economy at a given point in history to produce industrial and agricultural output, undertake capital construction, transport freight, and provide services to the population.

Economic potential is determined by the quantity of labor resources and the quality of their vocational training, by the volume of production capacities of industrial and construction organizations, by the production capacities of agriculture, by the extent of transportation arteries and the means of transport, by the development of sectors in the nonproduction sphere, by advances in science and technology, and by the resources of explored mineral deposits—in other words, by the elements that in their aggregate make up the productive forces of society. Economic potential depends on the extent of a country's national wealth.

Economic potential is a social category. Under the conditions of capitalism, economic potential is a factor in the economic and military pressure exerted on countries in the socialist community, in the economic and political subordination of countries with poorly developed economies, in the struggle for markets, and in the realization of superprofits. It is also a means of increasing the influence of monopoly capital on state administrative bodies and increasing the exploitation of the working masses. Economic potential depends on the absolute production capacity of economic branches and on the degree to which the capacities are used. Labor resources and production capacities in capitalist countries are not fully used because of certain patterns of reproduction. (It is estimated that in 1976 the USA had more than 8 million unemployed and industrial production facilities were operating at approximately 77 percent of capacity.) Economic potential is therefore calculated on the basis of the actual output and total use of production capacities.

Under socialism, economic potential is used to ensure the economic independence and defensive capability of socialist countries and the better satisfaction of the needs of the working masses by raising the living standard and cultural level of the people. Since economic potential is defined with respect to absolute production volume, a high economic potential may be enjoyed by large countries with developed productive forces and great national wealth. In 1977 the USSR produced one-fifth of the world's total industrial output and occupied second place in the volume of industrial production.

Labor resources and the level of vocational training are a key element in economic potential. In 1977, 92 percent of the able-bodied population was employed in the national economy of the USSR. Industrial and nonindustrial workers numbered 106.4 million, of whom 10.0 million had higher education and 14.0 million had specialized secondary education. Nearly 34.2 million industrial and nonindustrial workers upgrade their qualification each year.

Economic potential is in large measure determined by the level of industrial development, in particular, the development of the machine-building industry, which supplies all branches of the national economy with the means of production (*see* ECONOMIC DEVELOPMENT, LEVEL OF). Soviet industry comprises 44,000 associations and enterprises that in 1977 manufactured products valued at 554 billion rubles. Industry employs 35.4 million industrial and nonindustrial workers. The growth rates of industrial production are more rapid than those of other branches and promote the growth of economic potential as a whole. Between 1940 and 1977 the gross social product of the USSR increased by a factor greater than 12; during the same period industrial output increased by a factor of 18.

In 1977, USSR agriculture had 27,000 kolkhozes and 20,000 sovkhozes; 217.7 million hectares were under cultivation, and the

number of livestock held totaled approximately 329 million head. Agriculture had at its disposal 2.4 million tractors, 692,000 grain-harvesting combines, 1.5 million trucks, and a large quantity of other equipment. Gross agricultural output in 1977 was valued at 123.5 billion rubles.

Capital construction promotes the growth of economic potential. The USSR has 24,400 construction organizations, which put 407.8 billion rubles' worth of fixed capital stock into operation between 1971 and 1975, 95.4 billion rubles' worth in 1976, and 98.2 billion rubles' worth in 1977. This capital included 250 new, large-scale state industrial enterprises, a large number of new shops and production facilities at existing enterprises, new livestock complexes and farms, roads, housing, schools, hospitals, and other projects. Construction organizations employ 8 million persons. They have 151,400 excavators, 44,000 scrapers, 165,300 bulldozers, and 200,500 mobile cranes.

The USSR has at its disposal a high-capacity transportation system that incorporates 270,000 km of railroad track (belonging to the Ministry of Railroads) and sidings (belonging to industrial enterprises and organizations); 689,000 km of surfaced roads; 162,100 km of oil and gas pipelines; and well-developed oceangoing, river, and air fleets equipped with modern means of transport. In 1977, the total freight turnover for all types of general-service transportation amounted to 5.6 trillion ton-kilometers; more than 26 billion tons of freight and 42 billion passengers were transported.

Scientific institutions (including higher educational institutions) make up the scientific and technical potential of the USSR. They employ approximately 1.3 million scientific workers (one-fourth of all scientific workers in the world), including 35,400 doctors of sciences and 353,400 candidates of sciences. In 1976 and 1977, 7,800 new models of machines, equipment, and instruments were developed and production technology was improved, thereby effecting a significant increase in the nation's economic potential.

The growth of the economic potential of the USSR is promoted by the country's vast reserves of explored mineral deposits, many of which, including iron ore, coal, and potassium salts, are the largest in the world.

Economic potential also depends on the degree of development of sectors in the nonproduction sphere—education, public health, and housing and municipal services—that ensure the reproduction and functioning of labor power. The USSR has 154,000 general education schools, 861 higher educational institutions, 4,300 specialized secondary educational institutions, 24,300 hospitals and health care facilities, extensive housing facilities, and other social and cultural facilities.

In the stage of developed socialism, economic potential is characterized by a high level of development of the productive forces, by a dynamic and proportional economic growth, by the increasing efficiency of production, by the integrated mechanization and automation of production, and by the improvement of qualification levels. The economic potential reached by the USSR has made it possible for the country to create a material and technical basis for socialism and to use the scientific and technological revolution to construct the material and technical basis for communism. The economic potential of the USSR is supplemented by the economic potential of other socialist countries; together they constitute the economic potential of the world socialist economic system. In 1977 all socialist countries combined accounted for more than 40 percent of the world industrial output. Their growth rates significantly surpass those of the capitalist countries, which results in an increase in the share of the socialist economy in world production.

M. N. GORSHKOV [29–1868–1]

ECONOMIC REFORM IN THE USSR, the transition that took place in the mid-1960's—after the March and September 1965 plenums of the Central Committee of the CPSU—to a new system of management based on improved centralized planning, broader use of economic management techniques, greater autonomy in the economic operation of enterprises and economic organizations, and workers' increased responsibilities, as well as great material incentives, in raising the efficiency of production.

The factors that led to the economic reform were the higher level of development and scale of production and the greater complexity of economic relations caused by the scientific and technological revolution; these circumstances demanded, on the one hand, greater concentration on the long-range problems of improving production and, on the other, a high degree of operational efficiency in day-to-day economic activity. The system of economic management that had evolved was now hindering the effort to increase the productivity of labor and the efficiency of production, thereby reducing the possibility of achieving rapid growth in the material and cultural level of the population and high scores in the economic competition with capitalism.

Fuller utilization of the advantages of socialist production required that improvements in centralized state planning of the economy be combined with a higher degree of economic autonomy, increased operational efficiency, and greater initiative on the part of enterprises, bringing the system of economic management in line with the modern material base established for large-scale mechanized production during the period of socialist construction. The economic reform represented a new stage in the improvement of socialist production relations—particularly the relations between society as a single economic organism and the enterprises as components of that organism—through consistent implementation of the principle of democratic centralism; the principle requires that centrally planned state management of the economy be combined with the development of local initiatives by the broad masses of working people.

The economic reform was marked by the transition to full profit-and-loss accounting and extensive use of such cost factors as price, profit, credit, and bonuses. Profit became a more important indicator in evaluating the performance of enterprises. The new procedure for allocating profit ensured a better match of the social, collective, and personal interests in the socialist economy. Profits were yielding more funds to enterprises for the improvement of production, higher material incentives, and better working and living conditions. The amount of funds left at the disposal of a given enterprise depends on its efficient utilization of the productive assets assigned to it and on the increased volume, better quality, and greater profitability of its products. Enterprises have been assigned greater responsibility in fulfilling their contractual obligations under the profit-and-loss accounting system. The principles of profit-and-loss accounting are also applied to the activity of the higher-level administrative agencies and in some instances even to the ministries.

In the realm of administration, the economic reform relieved the state agencies of responsibility over the detailed operations of enterprises and allowed the centralized leadership to focus on the major long-range questions—namely, the development of production and, in addition, the broader application of economic management techniques that would ensure greater production efficiency by directly affecting the producers' economic interests. An important part of the economic reform was the restoration and strengthening of branch management and reduction in the number of management units through the establishment of production associations, production research associations, and all-Union (republic) industrial associations. The increased funds placed at the disposal of enterprises have enhanced the economic significance of the trade unions and other workers' organizations operating within the enterprises. The economic reform served to promote socialist competition.

Centralized planning assumed greater importance in the course of the economic reform. The improvement in the centrally ratified plan indicators of enterprise activity, as well as the reduction in the number of such indicators, enabled the state planning agencies to devote their concentrated efforts to the proportions and rates of development of the national economy, the basic direction of scientific and technological advances, and the rational siting of production. The planning functions of the enterprises (associations) and ministries were expanded, and production units were given greater operational economic autonomy and initiative. The introduction of new indicators and norms—such as the capital charge, fixed (rent) payments, and norms governing

the establishment of incentive funds—ensured that planning would be closely linked to economic incentives.

The reform of wholesale prices was an important component of the economic reform. Effective profit-and-loss accounting demanded that prices more fully reflect the socially necessary labor expenditures on production, that unprofitable operations in various branches of the national economy be eliminated, and that prices be more effectively used to improve the quality of products and modify the product mix. The reform of wholesale prices (1967) made it possible to plan prices in terms of the capital-output ratio of production.

With the economic reform, the use of commodity-money relations and cost categories in the national economy was substantially expanded. Bourgeois economists tried to use this circumstance to distort the content of the reform; they interpreted the reform as the abandonment of the foundations of socialism, as a denial of the Marxist-Leninist principles of economic construction of the new society, as an evolutionary step toward capitalism, as a kind of "liberalization" of socialism, or as evidence of the "convergence" of the two systems. Events have shown, however, that the economic reform represents the further development of the specific forms of organization of socialist production and is directed toward the improvement and consistent implementation of the management principles developed by V. I. Lenin and enriched by the practice of economic construction in the USSR and in the other socialist countries.

The economic reform was a factor in the greater efficiency of social production and in the growth of the country's economic potential in the stage of advanced socialism. On the other hand, improvements in economic relations are not limited to those achieved within the framework of the economic reform. The course of communist construction is marked by continuing efforts to further improve the mechanism and techniques of economic management.

A. S. DIESPEROV [29–1833–1]

ECONOMIC REGION, a territorial component of a country's national economy. It is characterized by a specific economic-geographical status, by an economic unity, by distinctive natural and economic conditions, and by a production specialization that is based on the territorial social division of labor and has developed over time.

Under capitalism, economic regions form and develop spontaneously in the heat of competition. When certain industries develop in one region, they frequently decline in another.

Under socialism, the territorial division of labor develops, and economic regions form in a planned fashion based on the economic laws of socialism. Economic regions are developed in a systematic and integrated manner; their specialization is combined with the rational location of productive forces and with the development of regional complexes of industries and production facilities that increase economic efficiency and ensure both that the natural, human, and technological resources of the regions will be used fully and that the economic potential of the nation will show an overall increase.

Marxist methodology was first applied to the study of economic regionalization by V. I. Lenin, who in *The Development of Capitalism in Russia* analyzed in depth the formation of economic regions in Russia, a process he regarded as an integral part of the development of capitalist production relations. In *New Data on the Laws of Capitalist Development in Agriculture*, Lenin provided a scientific basis for the division of the USA into three large economic regions: the industrial North; the South, formerly a slaveholding region; and the West, which was being colonized.

The scientific principles of socialist economic regionalization were first developed in the USSR. After the October Revolution of 1917 economic planning required that the country be scientifically divided into economic regions—parts of the national economy that would undergo systematic development. In 1920 the plan of the State Commission for the Electrification of Russia (GOELRO) established eight large regions.

With the organization of Gosplan (State Planning Commission) in 1921, the division of the country into economic regions was carried out by a special subcommission under the direction of G. M. Krzhizhanovskii and I. G. Aleksandrov; many directives on this question were issued by Lenin. In 1921, Gosplan drafted a plan that divided the country into 21 economic regions. The draft was revised by a commission (chairman, M. I. Kalinin) of the All-Russian Central Executive Committee. "Regionalization," the commission noted, "must be based on the economic principle. A region must be a distinctive and, as far as possible, economically complete, territory of the nation; it must have a specific combination of the requisite natural features, cultural heritage, and a population trained for production to become a link in the overall chain of the national economy" (*Ekonomicheskoe raionirovanie Rossii*, 1922, p. 55).

Specialization within the social territorial division of labor plays the principal role in the formation of economic regions. The general boundaries of a region are determined primarily by the range of action of specialized branches of the economy and major auxiliary facilities—the associated cooperative suppliers of raw materials, assemblies, and parts. In addition the formation of economic regions is influenced by natural conditions, such as the presence of large deposits of minerals, the hydroelectric potential, the natural fertility of the soil, and the climate. Also important is the nature of the work force, major considerations being population density, cumulative work experience, the ethnic composition of the population, and the extent to which the population is concentrated in large cities. Other factors influencing the formation of economic regions are technical and economic conditions, including the level of development of productive forces, the state of the production-related and social infrastructure, and the existence of such advanced forms of the social organization of production as concentration, specialization, and combination. The division of the country into administrative and political units also plays a part in the formation of economic regions, because of the important role of the socialist state in organizing economic construction. Territorial-production complexes constitute the material and technical basis for the formation of economic regions.

Given the vast expanses, varied natural conditions, and rich resources of the USSR and in view of the increased scale and complexity of the socialist economy, the country must be divided into both large and small economic regions in order to rationally organize the economy on a territorial basis. In practice, three levels of economic regions are distinguished: large (macroregions), administrative (mesoregions), and lowest-level (microregions).

Large economic regions comprise three types: Union republics, groups of Union republics, and groups of autonomous republics, krais, or oblasts of the RSFSR and the Ukrainian SSR. The large economic regions provide the framework for establishing national economic territorial proportions and for determining basic trends in the location of productive forces throughout the national economy.

Administrative economic regions, which form the basis of the country's territorial makeup, include autonomous republics, krais, and oblasts, as well as Union republics that are not divided into oblasts. Such regions constitute the basic elements in the territorial planning and management of the national economy.

Lowest-level economic regions are low-level administrative regions that constitute the primary territorial elements in the classification of economic regions.

The rapid development of the country's productive forces, the growth of the economic potential of the eastern and northern regions, the formation and development of new territorial-production complexes, and the implementation of large-scale integrated territorial programs make it necessary to revise periodically the network of economic regions in the USSR. These factors also require that the network be coordinated with efforts to improve the management and planning of the national economy for the purpose of accelerating the rate and increasing the efficiency of social production.

The network of economic regions has been revised several times, the number of large economic regions has changed, and the composition of some large regions has been altered. The first five-year plan (1929–32) was drawn up for 24 regions and the second five-year plan (1933–37) for 32 regions and the Northern Zone. The third five-year plan (1938–42) was compiled for nine regions and ten Union republics; at the same time, oblasts and krais were grouped into 13 primary economic units that formed the basis for planning the development of the national economy by region.

The system of classification approved in 1963 and updated in 1966 comprises, in addition to the Moldavian SSR, 18 large economic regions. Ten of these regions are in the RSFSR: Northwestern, Central, Volga-Viatka, Central Chernozem, Volga, Northern Caucasus, Ural, Western Siberian, Eastern Siberian, and Far East. Three regions are in the Ukrainian SSR: Donets-Dnieper, Southwestern, and Southern. The five remaining regions are formed from the other Union republics: Baltic (Lithuanian, Latvian, and Estonian SSR's), Transcaucasian (Georgian, Azerbaijan, and Armenian SSR's), Middle Asian (Uzbek, Kirghiz, Tadzhik, and Turkmen SSR's), Kazakhstan (Kazakhstan SSR), and Byelorussian (Byelorussian SSR).

Economic-geographical zoning—the establishment of economic-geographical zones, or consolidated regions—is used for the long-range forecasting of the placement of productive forces. Seven such zones were created during the drafting of *Basic Trends in the Development of the National Economy of the USSR Between 1976 and 1990*: Central and Northern European (Northwestern, Central, Volga-Viatka, Byelorussian, and Baltic large economic regions), Southern European (Central Chernozem, Northern Caucasus, Donets-Dnieper, Southwestern, Southern, and Transcaucasian large economic regions and the Moldavian SSR), Ural-Volga, Siberian, Far East, Kazakhstan, and Middle Asian.

ECONOMIC REGIONALIZATION, the demarcation on a national scale of economic regions that have formed or are forming in accordance with the territorial social division of labor (*see* DIVISION OF LABOR). Under socialism, a scientifically grounded economic regionalization is a necessary instrument of national economic planning by territory and is an important condition for improving the territorial organization of productive forces and economic management.

Economic regionalization is an effective method of management and an important factor in correctly combining territorial planning with the sectoral principle of management, in ensuring the rational location of productive forces, and in regulating the specialization and integrated economic development of economic regions in order to bring about every possible increase in the efficiency of social production (*see* ECONOMIC REGION, LOCATION OF PRODUCTIVE FORCES, and TERRITORIAL-PRODUCTION COMPLEX).

[29–1877–1]

ECONOMICS, a branch of science that studies production relations or the specific aspects of production relations in a given sphere of social production and exchange.

As a field of human knowledge, economics entails (1) the study of the objective laws governing the economic structure of society within the framework of the socioeconomic formations that regularly follow and replace one another, (2) the theoretical analysis of the processes and phenomena in the various spheres and branches of the national economy, and (3) the elaboration of practical recommendations with respect to the production and distribution of the necessities of life. Economics is one of the social sciences. The economic sciences are the product of long-term historical development. The establishment of a system of economic knowledge was directly tied to the advent of political economy as a science.

Works by classical bourgeois political economists laid the scientific foundation for the development of the economic sciences; such works investigated many important socioeconomic processes in the capitalist economies. The consolidation of the capitalist mode of production, the increasingly antagonistic opposition between hired labor and capital, and the transformation of the bourgeoisie from a progressive into a reactionary class contributed to the emergence of vulgar bourgeois political economy, which supplanted the analysis of the internal laws of the capitalist economic system with the description and systematization of externally perceived economic processes and phenomena.

The possibility of creating a genuinely scientific system of economic knowledge arose with the advent of Marxist economic doctrine, which incorporated the highest achievements of previous economic thought and creatively reworked them in accordance with materialist historical principles. F. Engels and V. I. Lenin made enormous contributions to K. Marx' economic theory. Marxist-Leninist economic theory was subsequently developed and concretized in the theoretical activity of the CPSU and of the fraternal Marxist-Leninist parties as well as in scholarly works by Soviet and foreign Marxist economists.

The Marxist system of classification differentiates between basic and applied economic sciences. The task of the basic sciences is to study objective economic laws and theoretically justify their effective application. The basic sciences include political economy, history of the national economy, history of economic thought, national economic planning, theory of economic management, statistics, accounting, and the analysis of economic activity. The applied sciences utilize the results of basic studies to solve specific practical problems. The various types of applied economic sciences are differentiated by function (finances and credit, money circulation, pricing, demography, labor economics, and material and technical supply), region or geographic area (economics of individual countries), and branch (for example, industrial, agricultural, construction, transport, or communications economics).

Political economy plays the principal role in the system of economic sciences, serving as the theoretical and methodological foundation of the entire complex formed by these sciences. Increased emphasis on the role of mathematics in economic research distinguishes the present stage of development of the economic sciences. In particular, the modeling of economic processes is being intensively developed. The socialist countries

make practical use of the theses, conclusions, and recommendations of the economic sciences in the drafting and implementation of economic policy.

For greater details on the development of economic science, see the relevant sections in articles on individual countries and Union republics and the section on economics in Volume 31.

ECONOMICS, CONSTRUCTION, in the USSR, the branch of economics that studies patterns of development and the effectiveness of capital construction. Before the Great Patriotic War of 1941–45, construction economics was regarded as part of the science of organization of construction production; only in the postwar years did it develop as an independent branch.

Construction economics deals with questions of the organizational forms of management (specialization, cooperation, concentration, combination, and the creation of production associations) and the planning of capital investment and construction production (forecasting and long-range, five-year, one-year, and routine operational planning of structure, location, and economic regionalization). An important task of the discipline is to substantiate the transition to the planning and evaluation of the performance of construction organizations on the basis of projects that are finished, turned over to the customer, and ready to operate.

Construction economics conducts research in the economic efficiency of capital investments and of scientific and technological progress in construction (factors, criteria, indicators, and planned standards) as the decisive prerequisite for increasing labor and capital productivity, improving the utilization of material resources, accelerating the growth of production capacities (primarily as a result of the reconstruction, technical reequipping, and modernization of enterprises), achieving the earliest possible use of new production capacities, and attaining projected technological and economic indicators.

Construction economics works out the economic principles underlying construction planning, the standardization of construction work, the industrialization of construction (with due regard to time, ecology, urban planning, and the social and economic impact), and the lowering of estimated costs and capital investments per unit of output. An important function of the discipline is to develop a system of interrelated cost and physical standards (planning, production, estimated, accounting, and statistical standards) for the technological and economic regulation and management of construction production in all phases of the investment process.

Construction economics studies the resources of capital construction and the effectiveness of their utilization, including questions relating to the development of the material and technical basis, fixed capital stock and its reproduction, the creation of normative circulating capital in the construction industry, the training and utilization of personnel, the organization and improvement of labor productivity, the improvement of the wage system, and the organization of the system of material and technical supply.

Construction economics substantiates economic methods of management and incentive in capital construction: profit-and-loss accounting (economic accountability), financing and crediting of construction, and the system of mutual settlements of accounts between participants in the construction process, stemming from efforts to bolster the role of economic incentive in the acceleration of scientific and technological progress.

Construction economics is associated with national economic planning, with a number of special economic disciplines (finance and credit, statistics, accounting, and analysis of economic performance), and with sciences that study the production technology of construction. It serves as a necessary methodological basis for determining the effectiveness of technical solutions to problems in the designing of construction projects and in the performance of construction work.

Construction economics is studied at a number of specialized scientific research institutes, such as the Scientific Research Institute of Construction Economics, the Central Scientific Research and Experimental Planning Institute of Automated Systems in Construction, and the All-Union Scientific Research and Planning Institute of Construction Labor. Economics sections (laboratories and departments) are found in virtually all planning and scientific research institutes working in the various areas of capital construction. Publications in the field include the journal *Ekonomika stroitel'stva* (Construction Economics) and the newspaper *Stroitel'naia gazeta* (Construction Newspaper); the publishing house Stroiizdat also publishes works on construction economics. Questions in construction economics are widely discussed in the Soviet press.

ECONOMICS, ENCYCLOPEDIAS AND DICTIONARIES OF, reference works that contain in a systematized form summaries of information on the economic sciences and on individual branches of economics. The following types of encyclopedias and dictionaries of economics are distinguished: general encyclopedias of economics, special encyclopedias that deal with individual branches of economic science, dictionaries that define terminology, and multilingual dictionaries of equivalent economic terms. The subject matter in encyclopedias of economics may be arranged either in alphabetical order or by topic; with rare exceptions, the organization of dictionaries of economics is alphabetical.

The first works that resembled dictionaries of economics appeared in the late 17th and early 18th centuries in Great Britain, Germany, France, and other European states. At first, such works were glossaries contained in monographs. For example, in Great Britain, E. Hatton included a "Merchant's Glossary" in *The Merchant's Magazine, or Trades-man's Treasury* (London, 1695; 9th ed., London, 1734). In the 18th century, encyclopedias and dictionaries of economics were first compiled as independent works. The immense 242-volume *Oeconomische Enzyklopädie, oder Allgemeines System der Staats-, Stadt-, Haus-, und Landwirtschaft, in alphabetischer Ordnung* (Berlin, 1773–1858) deserves special mention. It was initiated by the German economist J. G. Krünitz, who edited 72 of the volumes. The Scotsman J. R. McCulloch, who wrote works on economics, compiled *A Dictionary, Practical, Theoretical, and Historical, of Commerce and Commercial Navigation* (London, 1832). By 1890, McCulloch's dictionary had been published in 30 editions in Great Britain and the USA.

Russia. In the 18th century, M. V. Lomonosov attempted to compile a lexicon of merchandising terminology. The results were published much later as *Kratkoe raspolozhenie sochiniaemogo ekonomicheskogo leksikona rossiiskikh produktov* (A Con-

cise Plan for a Compiled Economic Lexicon of Russian Commodities; St. Petersburg, 1865) and *Reestr rossiiskim produktam* (A Register of Russian Commodities; St. Petersburg, 1869). Various encyclopedias and dictionaries of economics were compiled in the fields of merchandising, commerce, finance, and accounting. They included I. S. Vavilov's *Spravochnyi kommercheskii slovar'* (Reference Dictionary of Commerce; St. Petersburg, 1856), A. I. Ipatov's *Kommercheskii slovar'* (Dictionary of Commerce; St. Petersburg, 1898), and I. P. Babenko's *Torgovo-promyshlennyi slovar'* (Dictionary of Commerce and Industry; St. Petersburg, 1900).

USSR. The publication of the first Marxist general encyclopedia of economics, *Ekonomicheskaia entsiklopediia: Politicheskaia ekonomiia* (Encyclopedia of Economics: Political Economy; vols. 1–2, Moscow, 1972–75), was begun in 1972. The editor in chief of the first two volumes was A. M. Rumiantsev. The encyclopedia deals with a wide range of theoretical problems in Marxist-Leninist political economy, as well as with problems of current interest pertaining to the planning and control of the national economy, economic analysis, finance, and statistics. It presents a critique of bourgeois economic theories and, for the first time, attempts to show the development of economic thought in various countries and by various peoples. The encyclopedia also deals with problems equally within the purview of the economic, sociological, and juridical sciences.

A list of some other important Soviet encyclopedias and dictionaries of economics follows.

Ekonomicheskaia entsiklopediia: Promyshlennost' i stroitel'stvo (Encyclopedia of Economics: Industry and Construction). A. N. Efimov, editor in chief. Vols. 1–3. Moscow, 1962–65. Intended mainly for personnel in industry and construction.

Ekonomicheskaia zhizn' SSSR: Khronika sobytii i faktov, 1917–1965 (Economic Life of the USSR: Chronicle of Events and Facts, 1917–1965). Vols. 1–2, 2nd ed. Moscow, 1967.

Politekonomicheskii slovar' (Dictionary of Political Economy). Moscow, 1964; 2nd ed., Moscow, 1972.

Finansovo-kreditnyi slovar' (Dictionary of Finance and Credit). Vols. 1–2. Moscow, 1961–64.

Statisticheskii slovar' (Dictionary of Statistics). Moscow, 1965. The first reference work in the USSR on all branches of statistical science and practice.

Entsyklopediia narodnoho hospodarstva Ukrains'koi RSR (Encyclopedia of the National Economy of the Ukrainian SSR), vols. 1–4. S. M. Iampol'skii, editor in chief. Kiev, 1969–72.

Ekonomichnyi slovnyk (Dictionary of Economics). Edited by P. Baqrii and S. Doroguntsov. Kiev, 1973.

Vorob'eva, S. A., and T. K. Molodid. *Russko-ukrainskii slovar' sotsial'no-ekonomicheskoi terminologii* (Russian-Ukrainian Dictionary of Socioeconomic Terminology), 2nd ed. Kiev, 1976.

Nasyrova, M. *Kratkii russko-kazakhskii tolkovyi slovar' sotsial'no-ekonomicheskikh terminov* (Concise Russian-Kazakh Defining Dictionary of Socioeconomic Terms). Alma-Ata, 1968.

Russko-moldavskii ekonomicheskii slovar' (Russian-Moldavian Dictionary of Economics). Kishinev, 1973.

Russko-litovskii slovar' ekonomicheskikh terminov (Russian-Lithuanian Dictionary of Economic Terms). Vilnius, 1966.

Other countries. A list of the leading encyclopedias and dictionaries of economics from the 18th to the 20th centuries follows.

18th century (chronological)

Chomel, N. *Dictionnaire oeconomique, contenant divers moyens d'augmenter et conserver son bien*, vols. 1–2. Lyon, 1709; 4th ed., Commercy, 1741.

Allgemeines oeconomisches Lexikon. Leipzig, 1731; 4th ed., vols. 1–2, Leipzig, 1764.

ECONOMICS, INDUSTRIAL, in the USSR, the branch of economic science that studies industry as an integrated system of interrelated branches, sectors, and enterprises, or associations. Industrial economics took shape with the advent of large-scale socialist industry, which constitutes its field of inquiry.

Industrial economics studies the various manifestations of the objective economic laws of socialism in industry and devises economic management systems and techniques designed to increase efficiency and improve the quality of performance in all the branches and units of industrial production. Industrial economics includes the economics of individual branches (including the coal, oil refining, natural gas, chemical, and food sectors, light industry, power generation, metallurgy, and machine building); each of these subdivisions of economics examines the economic designation of products, material and technical base, and personnel makeup of the particular branch, as well as interbranch relations and branch differences with respect to fixed capital stock, circulating productive capital, makeup of production costs, and types of enterprises (including differences in size, level of specialization, location, and organization of labor and production).

The complexity of production activities of modern industrial enterprises has given rise to a separate scientific discipline known as enterprise economics ("the organization, planning, and management of the enterprise"). Enterprise economics explores the problems pertaining to the economic operations of the enterprise, or association, and to the state's guidance of its activity, and it studies rational methods of combining all elements of the production process toward their optimum utilization.

Industrial economics is related to several allied fields of knowledge—namely, national economic planning, statistics, labor economics, economic geography, finance and credit, and pricing—as well as to the technical and mathematical sciences.

Research studies of industrial economics are undertaken in the academic institutions, in the scientific institutions of the various branches, in the institutions of higher education throughout the country, and in various subdivisions of the institutes of the Academy of Sciences of the USSR and of the Union republics. Each of the branch research institutes is engaged in research on the economics of a given branch of industry. Various technical institutions of higher education have departments of industrial economics and departments of economics of individual branches of industry; these departments investigate problems related to the economics, planning, organization, and management of industrial production. Research studies are chiefly concerned with economic efficiency of production, the rational use of natural resources as industry's raw-material base, and the optimization of planning and operational decisions and techniques for improving the management of industrial production and of its branches, associations, and enterprises.

The major press organs that publish industrial economics research studies are the journals *Voprosy ekonomiki, Planovoe khoziaistvo, Ekonomika i organizatsiia promyshlennogo proizvodstva, Ekonomicheskie nauki*, and the collection of abstracts *Ekonomika promyshlennosti*. All the central scientific and technical journals of the various branches of industry have special sections devoted to the industrial economics of the given branch.

L. I. ITIN [29–1802–1]

ECONOMICS, INSTITUTE OF (full name, Institute of Economics of the Academy of Sciences of the USSR), a scientific institution that deals with fundamental problems of the political economy of socialism. The institute was organized in Moscow in 1930 from the economics section of the Communist Academy. Since 1936, it has been subordinate to the Academy of Sciences of the USSR.

As of 1978, the Institute of Economics had six departments, specializing in the following: general problems of the political economy of socialism; theoretical problems of the material and technical basis for communism and of scientific and technological progress; socialist reproduction; agrarian problems of socialism; the generalization of experience in Soviet economics and the history of the development of Soviet economic thought; and planning, coordination, and information. The institute also had a laboratory for the theoretical study of the planned management of the national economy, a general Academic Council, five academic councils for special problems, and three specialized councils for awarding the academic degrees of doctor of sciences and candidate of sciences.

The Institute of Economics helps draft five-year plans and long-range plans for the development of the national economy. It investigates theoretical problems pertaining to the improvement of planning techniques, planned pricing, and the management of the national economy, as well as problems of increasing the economic efficiency of social production, accelerating technological progress, and raising the efficiency of agricultural production. The institute generalizes the experience of economic policy and the development of economic thought in the USSR and in other socialist countries; it also prepares critiques of bourgeois and revisionist concepts of socialism.

The institute has a library. Graduate degrees are awarded for full-time study at the institute or for correspondence study. Since 1950, the institute has been a center for the coordination of economic research.

The Institute of Economics has its own press organ, the monthly journal *Voprosy ekonomiki* (Problems of Economics). The institute maintains broad scholarly relations with economic institutions in other countries.

V. V. ORESHKIN [29–1809–1]

ECONOMICS, JOURNALS OF, periodicals devoted to various aspects of economic theory and practice.

Prerevolutionary Russia. Before the advent of specialized economic journals in Russia, articles on economics were printed in general political and literary journals. Scholarly publications resembling journals of economics were issued under such titles as *Trudy* (Transactions) and *Vedomosti* (Bulletin) by various scholarly societies and economic institutions, for example, the Ministry of Finance, the State Bank, and the Ministry of State Domains. The first such publication was *Trudy Vol'nogo ekonomicheskogo obshchestva* (Transactions of the Free Economic Society; 1765).

In 1857, *Ekonomicheskii ukazatel'* (The Economic Index) first appeared. It dealt with both practical problems of agriculture and commerce and theoretical problems of political economy, statistics, and finance. The journal devoted special attention to theoretical and practical problems pertaining to the economic development of Russia, for example, raising the technical level of production and increasing the level of consumption.

A list of some Russian journals of economies that were published in the second half of the 19th century and the early 20th century follows.

Torgovyi sbornik (The Commercial Collection; 1864–73)
Vestnik finansov, promyshlennosti i torgovli (Journal of Finance, Industry, and Commerce; 1884–1917)
Russkoe ekonomicheskoe obozrenie (Russian Economic Review; 1897–1905)
Narodnoe khoziaistvo (The National Economy; 1900–05)
Kommercheskii mir (The Commercial World; 1906–09)
Promyshlennost' i torgovlia (Industry and Commerce; 1908–17)
Torgovo-promyshlennoe obozrenie (Commercial and Industrial Review; 1908–12)
Vestnik kooperatsii (Journal of Cooperation; 1909–18)
Ekonomist Rossii (The Russian Economist; 1909–12)
Novyi ekonomist (The New Economist; 1913–17)
Promyshlennaia Rossiia (Industrial Russia; 1915–16)

G. I. MASTEPANOVA

Since the October Revolution. The first central Soviet journal of economics was *Narodnoe khoziaistvo* (The National Economy; 1918–22), an organ of the Supreme Council on the National Economy (VSNKh). It contained theoretical articles that summarized the experiment in socialist administration and the processes involved in the socialist reorganization of the economic system. The journal also printed surveys of the current state of the economic system as a whole and of its individual sectors, discussions and debates in the VSNKh and in its departments and commissions, decrees of the Council of People's Commissars and of the VSNKh on economic matters, and the minutes and resolutions of congresses of the councils of the national economy. From 1920 to 1928, *Vestnik truda* (Journal of Labor) was published. An organ of the All-Union Central Council of Trade Unions, the journal dealt with the productivity of labor, the accounting of labor input and production output, labor conditions, wages, supply, the prices of consumer goods, and the everyday life of workers. *Vestnik statistiki* (Journal of Statistics), an organ of the Central Statistical Board, first appeared in 1919.

Problems of political economy, the methodology of economic science, and the most important problems of current economic policy received prominent coverage in the party press, especially in *Bol'shevik* (The Bolshevik; since 1924), *Vestnik sotsialisticheskoi akademii* (Journal of the Socialist Academy; founded in 1922, issued from 1924 to 1935 under the title *Vestnik kommunisticheskoi akademii* [Journal of the Communist Academy]), *Pod znamenem marksizma* (Under the Banner of Marxism; 1922–44), and *Sotsialisticheskoe khoziaistvo* (The Socialist Economy; 1923–30). *Planovoe khoziaistvo* (The Planned Economy; since 1924, publication suspended from 1941 to 1944) and *Vestnik promyshlennosti, torgovli i transporta* (Journal of Industry, Trade, and Transport; 1922–26) were devoted to theoretical and practical problems of, for example, national economic planning, regulation, and price formation. Theoretical and practical problems of state finances, credit, and money circulation were considered

in such journals as *Vestnik finansov* (Journal of Finance; 1922–30), *Finansovye problemy planovogo khoziaistva* (Financial Problems of the Planned Economy; 1922–30), and *Finansy i narodnoe khoziaistvo* (Finances and the National Economy; 1926–30). *Ekonomicheskoe obozrenie* (Economic Review; 1923–30), which was issued by the newspaper *Ekonomicheskaia zhizn'* (Economic Life), dealt mainly with current economic policy and observations of market conditions.

In 1922, *Ekonomist* (The Economist) and *Ekonomicheskoe vozrozhdenie Rossii* (Economic Rebirth of Russia) were published for a short time. Economists maintaining essentially bourgeois-restorationist positions grouped around the two journals; as a result, the publications were shut down. In the 1920's and 1930's, several dozen economic journals were issued at various times in the Union republics other than the RSFSR. However, in most cases, such journals were short-lived, appearing for only one to two years.

In the 1920's, together with central and republic journals of economics, a large number of local journals appeared. Such local journals were the organs of provincial executive committees, councils of the national economy, cooperatives, and trade unions. They included *Ekonomicheskoe stroitel'stvo* (Economic Construction; Moscow, 1922–30), *Promyshlennost' i torgovlia* (Industry and Trade; Leningrad, 1922–26), *Khoziaistvo Severo-Zapadnogo kraia* (The Economy of the Northwestern Krai; Leningrad, 1924–27), *Viatsko-Vetluzhskii krai* (Viatka-Vetluga Krai; Viatka, 1925–28), *Severnoe khoziaistvo* (The Northern Economy; Arkhangel'sk, 1923–29), and *Azovo-Chernomorskii krai* (Azov–Black Sea Krai; Rostov-on-Don, 1922–35). Such journals printed information relating to local economic life and articles on the economics of agriculture, industry, and trade. They also published surveys of local market conditions and featured discussions of timely problems pertaining to labor payment, financing and crediting, management in local industry and trade, and the location of production.

In the late 1920's and early 1930's, the number of economic journals was reduced. The leading theoretical journal of economics in the period was *Problemy ekonomiki* (Problems of Economics, 1929–41); it was published by the Institute of Economics of the Communist Academy, and from 1936 by the Academy of Sciences of the USSR. Problems of economic construction in industry, trade, and credit and monetary relations during the industrialization of the national economy were discussed in such journals as *Puti industrializatsii* (Paths to Industrialization; 1928–31), *Kredit i khozraschet* (Credit and Profit-and-Loss Accounting; 1932–38), *Khozraschet* (Profit-and-Loss Accounting; 1931–32), *Plan* (The Plan; 1933–37), and *SSSR na stroike* (The USSR Under Construction; 1930–41). Theoretical and practical problems of the transformation in agriculture were discussed in such journals as *Na agrarnom fronte* (On the Agrarian Front; 1925–35), *Agrarnye problemy* (Agrarian Problems; 1927–35), and *Ekonomika sel'skogo khoziaistva* (Agriculture Economics, since 1921).

During the Great Patriotic War of 1941–45, the publication of economic journals was virtually discontinued. After the war, the periodical literature on economics was quickly restored and enlarged.

In the mid-1970's, various journals of economics were published in the USSR. *Voprosy ekonomiki* (Problems of Economics; since 1948) deals with problems of economic theory, primarily with the political economy of socialism. It contains theoretical articles and provides broad coverage of management problems of current interest. The political economy of socialism and of modern capitalism, the history of the national economy, and the history of economic thought are discussed in *Ekonomicheskie nauki* (Economic Sciences; since 1958), *Izvestiia Akademii nauk SSSR: Seriia ekonomicheskaia* (Proceedings of the Academy of Sciences of the USSR: Economics Series, since 1970), *Vestnik Moskovskogo universiteta: Seriia 6—Ekonomika* (Journal of Moscow University: Series 6—Economics; since 1946), and *Vestnik Leningradskogo universiteta: Ekonomika, Filosofiia, Pravo* (Journal of Leningrad University: Economics, Philosophy, Law; since 1946). *Mirovaia ekonomika i mezhdunarodnye otnosheniia* (World Economics and International Relations; since 1957) and *SShA—Ekonomika, Politika, Ideologiia* (The USA: Economics, Politics, Ideology; since 1970) deal with problems in the theory of monopoly capitalism.

Problems of current interest in national economic planning and economic problems pertaining to individual sectors or to all sectors of the national economy are considered in the following journals: *Planovoe khoziaistvo* (The Planned Economy; since 1924), *Material'no-tekhnicheskoe snabzhenie* (Material and Technical Supply; since 1966), *Sotsialisticheskii trud* (Socialist Labor; since 1956), *Ekonomika i matematicheskie metody* (Economics and Mathematical Methods; since 1965), *Ekonomika i organizatsiia promyshlennogo proizvodstva* (The Economics and Organization of Industrial Production; since 1970), *Ekonomika stroitel'stva* (Construction Economics; since 1959), *Bukhgalterskii uchet* (Accounting; since 1937), *Vestnik statistiki* (Journal of Statistics; since 1919), *Den'gi i kredit* (Money and Credit; since 1927), *Finansy SSSR* (Finances of the USSR; since 1926), *Vneshniaia torgovlia* (Foreign Trade; since 1921), *Sovetskaia potrebitel'skaia kooperatsiia* (Soviet Consumers' Cooperative; since 1957), and *Sovetskaia torgovlia* (Soviet Trade; since 1927).

The following journals of economics are published in the Union republics: *Ekonomika Sovetskoi Ukrainy* (Economy of the Soviet Ukraine; Kiev, since 1958; in Russian and Ukrainian), *Narodnoe khoziaistvo Kazakhstana* (National Economy of Kazakhstan; Alma-Ata, since 1926), *Liaudies ūkis* (National Economy; Vilnius, since 1958), *Izvestiia Akademii nauk Azerbaidzhanskoi SSR: Seriia ekonomicheskikh nauk* (Proceedings of the Academy of Sciences of the Azerbaijan SSR: Economic Sciences Series; Baku, since 1966; in Russian and Azerbaijani), *Hayastani zhokhovrdakan tntesutyun* (National Economy of Armenia; Yerevan; since 1957, in Armenian), and *Ekonomika i zhizn'* (Economics and Life; Tashkent, since 1959).

Venezuela
Orientación económica (Caracas, since 1961).

L. I. SAVINSKAIA [29–1844–2]

ECONOMICS AND POLITICS IN THE ERA OF THE DICTATORSHIP OF THE PROLETARIAT, an article by V. I. Lenin containing scientific substantiation of the chief economic and political principles of the proletarian state in the transitional period between capitalism and socialism. Written on Oct. 30, 1919, the article was first published in *Pravda* (no. 250, Nov. 7, 1919). The article appears in Lenin's *Collected Works* (V. I. Lenin, *Poln. sobr. soch.*, 5th ed., vol. 39).

In the first part of the article, Lenin cites the Marxist tenet that an entire historical era lies between capitalism and communism, combining various features of these two social formations, and he describes the general and particular traits marking the development of various countries in the period of transition. Russia's basic forms of social economy—capitalism, petty commodity production, and communism—and corresponding social classes—the bourgeoisie, the petite bourgeoisie (the peasantry in particular), and the proletariat—were the same as those of any other country taking the road to socialism. But the dictatorship of the proletariat in Russia differed in certain particulars, which reflected the country's level of economic development and its petit bourgeois character. As Lenin pointed out, however, "the peculiarities can apply only to what is of lesser importance" (*Poln. sobr. soch.*, 5th ed., vol. 39, p. 272).

Lenin emphasized that the peasant economy's petty commodity production represented a very broad, sound, and deep-rooted basis for the revival of capitalism in its fierce struggle against communism—a struggle that took the form of private speculation and profiteering versus state distribution of products. Lenin's theoretical propositions are illustrated by factual data. He formulates and explains the thesis that "socialism means the abolition of classes" (*ibid.*, p. 276). In order to abolish classes it is necessary, first, to overthrow the landowners and capitalists. But this is only a part, and not even the most difficult part, of what needs to be done. It is necessary, second, to abolish the difference between workers and peasants. This task is incomparably more difficult and necessarily of long duration. It can be accomplished only by shifting from individual and isolated petty commodity production to large-scale social production. This transition will be accelerated by affording the peasant such assistance as will radically change all farming techniques. Hasty and incautious administrative and legislative measures can only delay and complicate the conversion of small peasant farms to a collective base.

At the same time that he advanced these most important principles, Lenin emphasized that the proletariat must separate and demarcate the working peasant from the peasant owner, the peasant worker from the peasant huckster, the peasant who labors from the peasant who profiteers. "In this demarcation lies the *whole essence* of socialism" (*ibid.*, p. 277).

The last section of the article describes changes in the status and interrelations of classes in the era of the dictatorship of the proletariat. Having overthrown the bourgeoisie and having won political power, the proletariat is transformed from an oppressed class into the ruling class. It wields state power, exercises control over the socialized means of production, guides the wavering and intermediary elements and classes, and crushes the resistance of the exploiters. The landowners and capitalists are defeated but not yet destroyed. They retain some of the means of production, and they still have vast social connections and the support of international capital. Because they have been defeated, the energy of their resistance has increased a hundred- and a thousand-fold.

On the basis of these circumstances, Lenin drew the conclusion that the bitter class struggle between the overthrown exploiters and the workers was at the time inevitable. The peasantry, "in view of the incredibly severe breakup of all social relations" (*ibid.*, p. 280), inevitably wavers and experiences uncertainty. The proletariat must strive to lead those who are vacillating and unstable and to influence and guide the peasantry. Lenin reveals the theoretical insolvency of the petit bourgeois views of R. MacDonald, J. Longuet, K. Kautsky, and F. Adler with respect to the transition to socialism "through democracy" in general; he demonstrates the basic difference between the bourgeois-democratic and socialist interpretations of equality, and he clarifies the Marxist position that equality becomes a prejudice if it is not understood as the abolition of classes.

The practice of socialist construction in the USSR and in the other socialist countries has confirmed the correctness of Lenin's theoretical statements regarding the main patterns of formation of socialist society, as presented in this article, and the need to consider the national peculiarities of any given country.

[29–1801–2]

ECONOMICS EDUCATION, in the USSR, the training of specialists in planning, accounting, finance, and other fields of economics to work in the national economy, research, and education.

Educational institutions offering instruction in economics arose in connection with the development of industry and trade. The first commercial schools were established in Russia in the second half of the 18th century. Economics courses were first taught in the country's universities in the 19th century. In the early 20th century, commercial institutes established in Moscow and Kiev were the first specialized higher educational institutions to train specialists for trade and industry.

Economics education began its true development after the October Revolution in 1917. During the years of Soviet power, a vast network of higher educational institutions specializing in economics, university departments of economics, technical and agricultural institutes, branches of economics institutes in industrial centers, and economics technicums has been established. Economics education is offered by day, evening, and correspondence study. The aggregate of academic courses of study required for each specialization is determined by the nature of the graduate's future job. Marxist-Leninist political economy is the methodological and general theoretical foundation of the training of economists. It fosters the formation of a communist world view in future specialists. The general courses of study common to all specializations in economics are the history of the CPSU, Marxist-Leninist philosophy and scientific communism, the history of the national economy, and the economic geography of the USSR and foreign countries, as well as courses in the technology of individual sectors of production and a foreign language. Students take a general course in higher mathematics and special courses in probability, statistics, and mathematical programming. Other mandatory studies include computers and computer programming, mechanized processing of economic information, and bookkeeping.

Specialization is available for the further training of economists. For example, students studying national economic planning may specialize in the planning of prices and prime cost, and those studying the economics of trade may specialize in the economics of food services or another area.

Economists are trained on the basis of a combination of theoretical learning and practical acquisition of work methods and procedures in a given specialization. Attention is focused on independent work by students and student participation in departmental research, student scientific societies, and the like. At the end of their final year of study, students at higher educational institutions of economics receive the qualification of economist and are assigned, according to the makeup of their training, to jobs in planning offices, offices of labor and wages, and supply offices at enterprises, ministries, and government departments, as well as to the systems of the Ministry of Finance, State Bank (Gosbank) and Central Statistical Board. Researchers and teachers in economics are trained in graduate study programs, which have been established at most higher educational institutions of economics and departments of economics. Technicums graduate specialists in planning, accounting, and merchandising with a secondary economics education. The training offered by technicums is narrower than that at higher educational institutions. Technicum graduates receive the qualification of planning technician, merchandising specialist, bookkeeper, and others.

Specialists working in economics, industry, agriculture, construction, and transportation may increase their knowledge in courses for advanced qualification offered at higher and secondary educational institutions, at institutes for improving the skills of managerial personnel and specialists, and through the network of universities of Marxism-Leninism and people's universities. The decree of the Central Committee of the CPSU of Aug. 31, 1971, On Improving the Economics Education of the Toiling Masses, played an important role in improving economics education, and a vast system of economics study at the higher, secondary, and elementary levels was set up in the country. Party organizations direct the work of all levels of economics study through councils on economics education. Methodological councils on the work of the schools of communist labor, which have become one of the large-scale forms of economics education, have been established at all trade union committees. The objective of mass economics education is to develop the labor activism of the toiling masses by every means possible.

Economists are trained in the USSR for many countries in Asia, Africa, and Latin America. Special attention is devoted to the economies of the particular countries. The Patrice Lumumba Peoples' Friendship University of Moscow is very helpful in this work.

ECONOMICS INSTITUTE OF THE STATE PLANNING COMMITTEE OF THE USSR (full name, Scientific Research Economics Institute of the State Planning Committee of the USSR; NIEI), a research institute that deals with methodological problems of long-range national economic planning and investigates the economic and social problems of development of the national economy of the USSR. The institute was established in Moscow in 1955. It has eight research departments and 32 sections (1976).

The institute's chief research activities are as follows: development of the methodology and techniques of compiling long-range national economic plans, including the methodology of economic forecasting and research on complex national economic problems with due regard for the creation and use of automated systems for planning calculations; refining of techniques of analytic research in economics; study of the problems of determining optimum long-term rates and proportions of socialist expanded reproduction, raising the efficiency of social production, and improving the standard of living; and elaboration of socioeconomic questions and proposals relevant to forming the economic and political design of long-range plans for the development of the national economy of the USSR.

The institute has a library and a mathematics laboratory. It trains graduate students in residence and by extension study. There are institute-wide scholarly councils that consider the most pressing problems and review candidate's and doctoral dissertations. In addition to basic monographs on fundamental problems, the institute regularly publishes collections of scientific articles on specific topics. L. M. RUMIANTSEVA [29–1867–1]

ECONOMICS INSTITUTES, in the USSR, higher educational institutions that train highly qualified economists and engineer-economists for various sectors of the national economy. Instruction is offered in many fields, such as the economics and planning of the national economy or of branches of industry, construction, transport, agriculture, or trade; the economics of labor and the planning of material and technical supply; computer processing of economic data; automatic control systems; economic cybernetics; merchandising and the organization of trade; the technology and organization of the food service industry; finances and credit; and accounting. The course of studies lasts from four to five years.

As of 1977–78, there were 36 economics institutes in the USSR with a four- or five-year course of instruction. They included 13 institutes of the national economy, 12 institutes of the economics of trade, four financial and economic institutes, two institutes of engineering economics (one in Leningrad and one in Kharkov), the Kuibyshev Planning Institute, the Moscow Finance Institute, the Moscow Institute of Economics and Statistics, the Saratov Institute of Economics, and the Sergo Ordzhonikidze Moscow Institute of Management, which was established in 1975 on the basis of the Sergo Ordzhonikidze Moscow Institute of Engineering Economics.

Most of the economics institutes have evening and correspondence divisions. Economists are also trained in the economics departments of universities and other higher educational institutions. (*See* ECONOMICS EDUCATION; MOSCOW INSTITUTE OF THE NATIONAL ECONOMY; LENINGRAD INSTITUTE OF ENGINEERING ECONOMICS; and LENINGRAD FINANCIAL AND ECONOMIC INSTITUTE.) [29–1853–1]

ECONOMICS INSTITUTES, RESEARCH, in the USSR, scientific institutions that conduct research in economics.

In Russia, the first specialized scientific institution that dealt with economic problems was the Commission for the Study of Natural Productive Forces, which was founded in 1915. After the Great October Socialist Revolution, economic problems of building socialism and of the world capitalist economy were studied at the Socialist Academy of Social Sciences, which was established in 1918 and renamed the Communist Academy in 1924. The Communist Academy included the Institute of World Economy and World Politics (founded 1925), the Agrarian Institute (1928), and the Institute of Economics (1930). Another institute of economics operated under the auspices of the Russian Association of Social Science Research Institutes (1924–30). In 1936, the economics institutes of the Communist Academy were placed under the jurisdiction of the Academy of Sciences of the USSR (AN SSSR).

As a scientific-organizational center, the economics division of the AN SSSR, which was established in 1962, coordinates the study of the economic regularities of building socialism and communism and the investigation of problems pertaining to optimum national economic planning and management, the economic efficiency of social production, the construction of the material and technical basis for communism, the scientific and technological revolution, the location of productive forces, the economics of contemporary capitalism, the world socialist system and the developing countries, and economic competition between the two world systems.

The following economics institutes are attached to the economics division of the AN SSSR: the Institute of Economics, the Institute of World Economics and International Relations, the Institute of the Economics and Organization of Industrial Production (Novosibirsk, 1958), the Institute of Africa, the Institute of Economics of the World Socialist System, the Institute of Latin America, the Central Economic Mathematical Institute, the Institute of the Far East, the Institute of the USA and Canada (1968), the Institute of Social Economic Problems (Leningrad, 1974), and the Institute of Economics of the Urals Scientific Center of the AN SSSR (Sverdlovsk, 1974).

The economics division of the AN SSSR supervises the work of the economics departments of the Yakut and Buriat branches of the Siberian Division of the AN SSSR and the economics departments of the Dagestan, Komi, S. M. Kirov Kola, Bashkir, and Karelian branches of the AN SSSR. The Association of Soviet Economic Scientific Institutions, which was founded in 1957, operates under the auspices of the AN SSSR.

The following economics institutes are attached to the State Planning Committee of the USSR: the Scientific Research Economics Institute of the State Planning Committee of the USSR, the Scientific Research Institute of Planning and Standards (1961), the All-Union Scientific Research Institute of Cybernetics (1969), and the Council for the Study of Productive Forces (1930).

In the Union republics, scientific research economics institutes have been established by the state planning commissions, branch economics institutes have been organized by major ministries, and institutes of economics are attached to the academies of sciences of the republics. Such institutes have operated in Byelorussia since 1931, the Ukraine since 1936, Lithuania since 1941, Uz-

bekistan since 1943, Georgia since 1944, Tadzhikistan since 1946, Latvia since 1946, Estonia since 1946, Kazakhstan since 1952, Armenia since 1955, Kirghizia since 1956, Turkmenistan since 1957, Azerbaijan since 1958, and Moldavia since 1960. The International Institute of Economic Problems of the World Socialist System has been located in Moscow since 1971.

Economic problems are studied in special laboratories and in departments or subdepartments at higher educational institutions —that is, at institutes of the national economy, planning institutes, financial and economic institutes, and institutes of engineering economics—and at universities, higher schools, and academies. The most important departments and subdepartments that deal with economic problems are the subdepartments of political economy at the M. V. Lomonosov Moscow State University, the A. A. Zhdanov Leningrad State University, and the University of Kiev, as well as the departments of political economy at the Higher Party School and the Academy of Social Sciences of the Central Committee of the CPSU.

V. V. ORESHKIN [29–1854–1]

ECONOMICS OF COMMUNICATIONS, in the USSR, the branch of economics that studies the patterns of the development and functioning of communications. It studies the forms and methods of economic management in order to improve the efficiency and qualitative performance of the branch as a whole and of the various subbranches, including postal, telegraph, and telephone communications.

As a discipline, the economics of communications proposes ways of improving the management of communications enterprises, makes recommendations on the methodology and organization of economic planning, and develops forms and methods for the organization of labor and production with due consideration given to the uneven work load of communications enterprises and networks. It also suggests methods for planning and analyzing the economic performance indicators of the communications branch and for evaluating their impact on production efficiency, and it makes recommendations for improving the system of tariffs for communications services and prices for the products of various communications enterprises (*see* TARIFFS, COMMUNICATIONS). Research in the economics of communications takes into account the fundamental economic characteristics of the sector (the nonmaterial nature of the product—communication services—and the participation of more than one communications enterprise in the transmission of messages).

The economics of communications is closely associated with national economic planning and with a number of allied economic sciences: communications statistics, the finances of communications, and so forth. The discipline also has important ties with specialized technical sciences. Research on problems of the economics of communications is carried out at research institutes and higher educational institutions of communications that have departments of the economics of communications and departments of the organization of planning and management. The scientific methodology of the discipline is widely used by economic planning agencies, ministries, enterprises, and research institutions in the field of communications to evaluate the effectiveness of capital investments and new communications technology and to plan and manage communications production. Research in the economics of communications is published in the journal *Vestnik sviazi* (Communications Journal).

O. S. SRAPIONOV [29–1803–1]

ECONOMICS OF THE WORLD SOCIALIST SYSTEM, INSTITUTE OF (full name, Institute of Economics of the World Socialist System of the Academy of Sciences of the USSR), a scientific institution dedicated to research on economic, political, and ideological issues in the development of world socialism and on the laws that govern the construction of a socialist society, the strengthening of the world socialist system, and the enhancement of the revolutionary influence of the world socialist system on world history. The institute, which was established in Moscow in 1960, had seven departments and 32 sections in 1977.

Research at the institute is devoted to (1) analyzing the general laws and stages in the construction of a new society in the other socialist countries; (2) providing a theoretical generalization of the experience obtained in the development of the world socialist system and a new type of international relations; (3) elucidating theoretical and practical questions pertaining to the development of a world socialist economy and socialist integration; (4) studying the international division of labor; (5) comprehensively analyzing the general and specific features of economic, political, and ideological life in the various socialist countries, conducting a comparative study of the theory and practice of economic construction in the other socialist countries, and assessing prospects for further strengthening the economic ties of such countries with the USSR; (6) analyzing the development in the socialist countries of theoretical thought on the construction of socialism and socialist economic integration; (7) and criticizing bourgeois, reformist, and revisionist ideas on issues relating to the development and mutual relations of the socialist countries.

The institute has a library. Graduate degrees are awarded for study at the institute and for correspondence study. An institute-wide academic council directs organizational and scholarly work. Specialized councils for awarding academic degrees confer the degrees of doctor of sciences and candidate of sciences. There is also a scholarly council for coordinating research on different aspects of the world socialist system.

The institute publishes basic monographs, pamphlets, and collections of scholarly works on problems in the development of the world socialist system as whole and on current problems in the development of individual socialist countries.

G. A. VLASKIN [29–1810–1]

ECONOMICS OF TRADE, in the USSR, the branch of economic science that studies patterns of development of consumer trade as a form of commodity circulation. The economics of trade studies the influence of trade on production and on supply and demand, investigates the correlation between increased volume of commodity turnover and the development of a material and technical basis for trade, and analyzes the interrelations between the size of the commodity supply, the rate and volume of commodity turnover, and the range of goods involved in commodity turnover.

With a view to increasing the efficiency of social production, introducing scientific methods of management, and providing improved service to the people, the economics of trade investigates problems in management and planning and in providing economic incentives in trade. In a developed socialist society, the economics of trade studies problems in such areas as the improvement—for all levels of the trade apparatus—of current planning, long-range planning, and the system of economic incentives. It seeks to determine the volume and structure of public consumption and investigates methods, based on the study of the incomes of individual population groups, for evaluating the effective monetary demand of the population. The economics of trade develops a scientific methodology for the planning of commodity turnover and for the formation and location of commodity supplies. It explores ways to economize actual and embodied labor in the circulation sphere, seeks out reserves of fixed capital stock and of circulating productive capital, and develops methods for making more efficient use of this stock and capital in trade.

The leading institution of the economics of trade—a discipline that is associated with such fields as national economic planning, economic geography, statistics, industrial economics, agricultural economics, transportation economics, the organization of trade, and trade management—is the All-Union Scientific Research Institute of the Economics of Trade and Management Systems. Problems of the economics of trade are also studied at the All-Union Scientific Research Institute for the Study of Demand and Market Conditions, the Scientific Research Institute of Food Services, the Central Scientific Research Institute of Scientific and Technical Information Pertaining to Trade, and the Ukrainian Scientific Research Institute of Trade and Food Service. Is-

sues in the economics of trade are studied at subdepartments of the economics of trade in the country's higher educational trade institutions and institutes of the national economy.

Theoretical and practical problems of trade are discussed regularly in the newspaper *Sovetskaia torgovlia* and in the journals *Sovetskaia torgovlia, Sovetskaia potrebitel'skaia kooperatsiia, Kommercheskii vestnik, Torgovlia za rubezhom*, and *Novye tovary*.

I. M. FEL'DMAN [29–1806–2]

ECONOMIC STATISTICS, the branch of statistical science that studies the quantitative aspect of economic processes and phenomena in the national economy in conjunction with their qualitative aspect. Unlike more specialized forms of statistics, which study economic processes in particular branches of the national economy, economic statistics studies the national economy as an integrated whole (*see* STATISTICS, INDUSTRIAL; STATISTICS, AGRICULTURAL; and STATISTICS, LABOR).

Marxist-Leninist political economy constitutes the theoretical foundation of economic statistics. Political economy investigates and identifies the most important features of social-production relations and reveals the laws governing the production and distribution of material goods; economic statistics makes use of these principles to provide a quantitative description of phenomena and processes in the national economy and shows, with the help of economic-statistical indicators, how social production is developing in a particular place and time. In V. I. Lenin's definition, the purpose of economic statistics is to give "statistical expression" to the phenomena and laws of socioeconomic development of society (see *Poln. sobr. soch.*, 5th ed., vol. 27, p. 206). A preliminary and comprehensive socioeconomic analysis of the phenomena under study is a major precondition for the scientific organization of economic statistics.

Economic statistics is both an integral part of statistical science and an important branch of practical activity. Although it emerged as an independent scientific discipline and a subject taught in educational institutions before the Great Patriotic War of 1941–45, economic statistics underwent its greatest development after the war. In the investigation of economic processes and in the collection, processing, and analysis of statistical data, it makes extensive use of such techniques as mass statistical observation, grouping, indexing, the analysis of time series, and the balance method. Mathematicoeconomic research methods involving computers are coming to be used more widely.

In a socialist society, economic statistics is an important tool in the management and planning of the national economy. It describes the condition and development of a socialist economy, progress toward the fulfillment of national economic plans, and the way the branches of the economy are developing in relation to one another. In addition, it provides a picture of the introduction of new technology, the location of productive forces in the country, and improvements in public welfare. The most important tasks of economic statistics include the economic-statistical description of the efficiency of social production and the improvement of performance at all levels of the national economy.

In bourgeois statistics, economic statistics does not exist as an independent scientific discipline for the integrated investigation of processes and phenomena of social reproduction. The statistical literature of capitalist countries treats economic statistics as the application of general methods of statistics and mathematical statistics to the measurement of economic phenomena.

The system of indexes in economic statistics comprehensively describes economic processes and phenomena. The crucial indexes—the comprehensive, general indexes of economic development and of the growth of the people's material prosperity—include the total social product, national income, real incomes of the population, nonproductive consumption, accumulation, national wealth and its constituent elements, and the social productivity of labor.

Statisticians dealing with particular branches of the economy apply the general principles that have been developed by economic statistics in order to construct a system of economic indexes and a methodology for calculating them. A major division of economic statistics is the balance of the national economy of the USSR, which makes it possible to ascertain whether the economy is developing in a balanced manner.

M. R. EIDEL'MAN [29–1835–1]

ECONOMIC TABLE (*Tableau économique*), the principal work by F. Quesnay, the founder of the Physiocrats; the first attempt to analyze social reproduction by establishing definite balanced proportions between the natural (material) and value elements of social production. *Economic Table* was written in 1758.

Economic Table sets forth the erroneous theory of the net product (*produit net*), which according to Quesnay is created only in agriculture, and divides society into three classes: the productive class (farmers and hired agricultural laborers), the proprietary class (landowners and the king), and the sterile class (industrialists, merchants, artisans, and hired industrial workers). Quesnay then describes the circulation of a year's product, a process that begins after the farmers have paid the landowners rent, which is considered the only form of net product, in the amount of 2 billion livres.

The process of circulation comprises the following five acts: (1) The landowners purchase 1 billion livres' worth of food from the farmers; as a result, 1 billion livres return to the farmers, and one-fifth of the year's product goes out of circulation. (2) The landowners use the remaining 1 billion of their 2 billion livres received in rent to buy industrial articles from the sterile class. (3) With the 1 billion livres received for its industrial articles, the sterile class buys food products from the farmers. A second billion livres is thus returned to the farmers, and two-fifths of the year's product goes out of circulation. (4) The farmers buy 1 billion livres' worth of industrial articles from the sterile class, which go toward the replacement of tools and materials whose value was included in the value of the year's product. (5) The sterile class uses its 1 billion livres to purchase raw materials from the farmers. The circulation of the year's product thus ensures the replacement of the capital (*avances*) used in agriculture and industry, and production can begin again.

K. Marx criticized the flaws and contradictions in *Economic Table*. Since it was based on the erroneous theory of the net product and an incorrect class division of society, the work did not reflect the mechanism of capitalist reproduction and its contradictions. The practical recommendations that came out of *Economic Table*, however, were progressive and antifeudal.

ECONOMISM, an opportunist trend in the formative period of Russian Social Democracy (late 19th and early 20th centuries) that sought to adapt the tactics and organization of Social Democracy to the spontaneous course of the working-class movement. "Its political essence was summed up in the programme: 'for the workers—the economic struggle; for the liberals—the political struggle'" (V. I. Lenin, *Poln. sobr. soch.*, 5th ed., vol. 26, pp. 343–44).

Among the leading Economists were K. M. Takhtaroev, S. N. Prokopovich, E. A. Kuskova, V. N. Krichevskii, A. S. Pikker (A. Martynov), and V. P. Makhnovets (Akimov). The major centers of economism were the newspaper *Rabochaia mysl'* and the journal *Rabochee delo* (the organ of the Union of Russian Social Democrats Abroad). Economism was the first manifestation of opportunism in Russian Social Democracy; it was a variety of

international opportunism—that is, of Bernsteinism. The spread and development of economism were promoted by (1) the absence of ideological and organizational unity among the Russian Social Democrats, (2) the insufficient degree of class consciousness on the part of the proletariat—a class that had just taken the first step on the path of independent struggle and was drawing recruits among the peasants, for whom the purely economic side of the struggle was the most comprehensible one, (3) the massive influx of petit bourgeois elements in the Social Democratic organizations, (4) the successful economic strikes during the period of the industrial upsurge, and (5) the arrests that eliminated the most experienced and theoretically well-trained revolutionaries.

The ideas of economism were first formulated in the first issue of the newspaper *Rabochaia mysl'*: "The struggle for economic status, the struggle against capital on the grounds of vital daily interests, and the strike as the instrument of this struggle—such is the motto of the workers' movement." The Economists, distorting the Marxist tenet that all class struggle is political struggle, maintained that any spontaneous action by the workers constitutes political action. According to the Economists, what was meant by political struggle was not the independent class struggle of the proletariat (destined to lead the bourgeois-democratic revolution) but legal opposition within the framework of the autocratic system and in alliance with other "oppositionist social strata" (for example, worker participation in the bureaus that had jurisdiction over the factories and in urban self-government and the submission of demands to the tsarist government for "protective labor legislation").

By denying the proletariat's need to voice its own political demands and to struggle for such demands, the "new school in Social Democracy" (as the Economists called themselves) subordinated the workers' movement to the liberal bourgeoisie. The economists exalted the spontaneity of the workers' movement and maintained that the proletariat would develop its own socialist awareness in the process of spontaneous struggle. They denied the necessity of a political party of the working class.

The Economists' basic ideas were most consistently and fully set forth in the *Credo*—a document written by Kuskova in the early part of 1899. The spread of economism in the Social Democratic movement led to the increasing organizational and ideological fragmentation of the local groups and committees of the RSDLP. As an expression of the ideas of bourgeois liberalism in the workers' movement, economism met with the decisive criticism of revolutionary Marxists on the one hand and with the approval of Russian liberals on the other.

Lenin struck the first blow against the newly formed trend of economism in February 1897, at a meeting between the "old men" and the "youths" of the St. Petersburg League of Struggle for the Emancipation of the Working Class; the "youths," who were influenced by "legal Marxism" and Bernsteinism, had assumed the leading positions in the league. In August 1899, from his exile in Shushenskoe, Lenin wrote "A Protest by Russian Social Democrats" (against the Economists' *Credo*). The "Protest," which was signed by 17 exiled Social Democrats, declared economism to be a manifestation of bourgeois influence on the proletariat and pointed out the close ties between economism and Western revisionism. In 1901 the newspaper *Iskra* took up the struggle against the Economists; the decisive role in the ideological defeat of economism was played by Lenin's book *What Is to Be Done?* (1902).

The influence of economism waned with the development of the workers' movement and the growing role of the *Iskra* supporters in the Social Democratic organizations. By 1903 only a few of the Social Democratic organizations continued to espouse economism. At the Second Congress of the RSDLP (1903) the delegates representing the Economists (members of the League of Russian Social Democracy Abroad and of the St. Petersburg Workers' Organization) opposed the inclusion in the party program of the point on the dictatorship of the proletariat and the introduction of socialist consciousness in the workers' movement. After the congress, most of the Economists became Mensheviks.

The struggle of the revolutionary Marxists against economism —a struggle headed by Lenin—was a necessary condition for the establishment of that new type of proletarian party which was the Bolshevik Party.

ECONOMIST, THE, a weekly British journal of politics and economics. *The Economist* has been published in London since 1843. As a rule it supports the Conservative Party. It is intended mainly for businessmen. Circulation, more than 100,000 (1977).
[29–1814–1]

ECONOMIZER, a component of a boiler unit. An economizer is a heat exchanger in which feed water is heated by flue gases before the water is supplied to the boiler. For a pressure of up to 22 kilograms-force per cm^2 (2.2 megapascals) and a feed-water temperature below the dew point of the flue gases or for water that has not been deaerated, an economizer consisting of plain cast-iron tubes or of finned cast-iron tubes is used. For higher temperatures and pressures, an economizer consisting of steel tubes is used; most economizers of this type consist of plain steel tubes. An economizer increases the efficiency of a boiler unit.
[29–1787–1]

ECONOMO, CONSTANTIN ALEXANDER VON (Baron von San Serff). Born Aug. 21, 1876, in Braila; died Oct. 21, 1931, in Vienna. Austrian neurologist of Greek descent.

Economo graduated from the University of Vienna medical school in 1901 and became a professor of neurology and psychiatry there in 1921. During World War I he served first as a pilot and then as an army medical officer.

In 1902, Economo discovered the swallowing and chewing centers of the brain. In 1917 he described epidemic encephalitis lethargica (Economo's disease), and on the basis of clinical and anatomical studies on the disease he determined the significance of the hypothalamus and thalamus in insomnia and advanced a theory of sleep.

In 1925, Economo published a book (with G. N. Koskinas) and an atlas on the cytoarchitectonics of the cerebral cortex. He compiled a precise cytoarchitectonic map of the cerebral cortex (109 areas) and measured the size of cells in the various cortical layers. Based on cytoarchitectonic research and the study of human fossil skulls, he put forth the theory of progressive cerebration, according to which the brain develops continuously, advancing to a higher stage of development. In 1931 he opened a special department for the study of the brain, mainly its cytoarchitectonics and myeloarchitectonics.

Economo became president of the Vienna Psychoanalytical Society in 1928. A pioneer in Austrian aviation, he became president of an aviation club in 1910.

ECONOMY. (1) The aggregate of production relations, or the economic basis of society. The scientific definition of the economy and of its place in the development of society was first given by K. Marx: "The aggregate . . . of production relations constitutes the economic structure of society, the actual base upon which the legal and political superstructure is erected and which has its particular corresponding forms of social consciousness" (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 13, pp. 6–7). The economy forms the basis of all other social relations and plays the decisive role in the development of society.

The economy is the system of production relations in any mode of production. The determining relations in this system are those

pertaining to the ownership of the means of production and the character and social means of linkage between the direct producers and the means of production. The aggregate of production relations of a given mode of production is expressed in the corresponding system of economic laws and categories of political economy. Each mode of production has its own characteristic economy with its own distinct type of ownership, objectives, and forms and methods of management—as in the case of the primitive communal system, slavery, feudalism, capitalism, and communism. Economics directly interacts with politics, a component of which is economic policy.

(2) The national economy of a given country or a given part of the economy including the corresponding branches and types of production. The national economy reflects not only the characteristic features of a given mode of production but also the distinguishing features of a given country stemming from such specific historical conditions as its geographic location, the part it plays in the international division of labor, its historical traditions, and the level of development of its productive forces.

The economy includes the branches of material production (such as industry, agriculture, construction, transport, and trade) and the nonproduction sphere (including education, health care, and culture). Social production is subdivided into (1) production of the means of production and (2) production of consumer goods. The relationship between the two subdivisions is influenced by various factors, with the first subdivision playing the decisive role as the basis of technological progress.

The economy of the USSR is a single national economic aggregate that encompasses all the elements of social production, distribution, and exchange throughout the country. It is based on large-scale mechanized production in all branches of the national economy and is developed on a planned basis for the benefit of the people's increasing well-being. The USSR has built an advanced socialist society. In its present stage, socialism is already developing on its own basis, and the full creative powers of the new system are increasingly revealed. The greater division of labor and more proportional development of the various branches and regions are creating the necessary conditions for consistent growth in the efficiency of all social production and for fuller utilization of natural and labor resources.

The entry of socialism into the world arena led to the emergence of the economy of the world socialist system. The chief trends in the development of this system are the growing extent of socialist economic integration, the increasing convergence of the national economies of the various socialist countries, and the establishment of far-reaching and stable bonds linking together the main branches of the economy and of science and technology.

ECONOMY OF TIME, LAW OF, a universal economic law that expresses the source of economically efficient social reproduction and the means by which such efficiency can be increased.

The law of economy of time was formulated by K. Marx in connection with the disclosure of the historically transitory significance of money—the latter being the manifestation of the social character of production in terms of value. Under communism, value will no longer be needed to ascertain and measure increasing efficiency, since this will be feasible by direct means. As Marx pointed out, "Comprehensive social as well as individual development, consumption, and activity depend on the saving of time. All economy is ultimately an economy of time. . . . Economy of time, like the planned distribution of work time among various branches of production, is still the first economic law based on collective production" (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 46, part 1, p. 117).

The law of economy of time is a scientific abstraction. Marxist science never projects this law directly onto specific economic phenomena; rather, it reveals the specific historical conditions and forms in which the law is operative for the various modes of production.

Economy of time includes economy of work time expended in a given period, as well as economy in the results of previous expenditures of work time, or work time expended on raw materials, supplies, machinery, equipment, and other means of production. Accordingly, some of the concrete effects of the law of economy of time are higher labor and capital productivity, lower material-intensiveness, and optimal proportionality in the national economy as well as within individual economic units.

As interpreted by Marx, the law of economy of time can be applied not only to work time but also to some nonworking time (that is, time spent on the performance of duties beyond the range of production proper). Under this interpretation, the law of economy of time is manifested in such concrete forms as the mechanization of housework, improvement of consumer services, and reduction in the amount of time expended on transportation, shopping, sewing clothes, and private housing repairs.

The law of economy of time may operate in spontaneous as well as in planned form. In the first instance the trend toward increased efficiency results from the interaction of resource losses and savings; in the second, the law of economy of time operates in the form of a policy of economies.

The mode of production is the decisive factor determining the law's nature and its socioeconomic effects, which are radically different under capitalism and under socialism. Under capitalism, economies of time are realized by private owners by means of increased exploitation. The law of economy of time assumes the particular form whereby scientific and technological advances and increasing economic efficiency tend to serve the interests of private capitalist appropriation. Surplus value and capitalist profit are the supreme criteria of economy.

In *Das Kapital*, Marx examined the historical actualization and antagonistic contradictions of the law of economy of time under capitalism. The unavoidable vices of capitalism—parasitic consumption on the part of the exploiting classes, unemployment, the anarchic formation of the proportions of the national economy, and the crises consequent thereto—preclude the attainment of maximum economic efficiency, and hence maximum economy of time. At the same time, subject to these general objective limitations, the economic efficiency of production under capitalism does increase. Capitalist management in practice, in addition to plundering resources, leads to the development of new techniques and methods of saving work time, raw materials, and supplies, reducing production costs, and improving the quality of products and services. These innovations, disassociated from socioeconomic forms unacceptable to socialism, are studied and assimilated by socialist enterprises, institutions, and organizations.

The socialist mode of production provides greater opportunity for the economical use of time and of all types of resources. Parasitic consumption by exploiters is eliminated, and reproduction is freed of the narrow criteria of efficiency foisted upon it by private ownership; the economical use of resources and the implementation of the law of economy of time are effected in the general form of planned reduction in the relative expenditures of live and embodied labor—that is, a policy of economies. The decisive factor in the law of economy of time is the development of reproduction on the basis of a single national economic plan, which permits the deliberate and constant maintenance of optimum proportions in the overall economy and in its branches. The system of branch and regional production plans ensures optimum reproduction at all levels.

Socialism is characterized by a set of uniform state policies with respect to technology—policies that also yield considerable savings of resources to society. Under the conditions of advanced socialism, when the advantages of the socialist system of management are combined with the gains of the scientific and technological revolution, the progress of reproduction is accelerated and acquires a complex character. Improvements in efficiency and quality take place at a faster rate; the socially necessary level of such improvements rises continuously and becomes mandatory for all producers. Obsolescence takes place at a more rapid pace, affecting technology, production techniques, the organization of production, and the finished product; every phase of social reproduction must be intensified. Consequently the time factor becomes increasingly important, thus in fact reflecting the specific effect of the law of economy of time under the conditions of mature socialism.

Under socialism, the socioeconomic effects of the law of economy of time are expressed in the reduction of time required to

produce the necessary product, this being the material prerequisite for the fuller and more comprehensive development and demonstration of man's creative endowments.

ÉCOSSAISE, a folk dance of Scottish origin performed to bagpipe music. The écossaise is a variety of contredanse, a dance common in Great Britain. It was performed as a ballroom dance in France beginning in the late 18th century. The musical time was first 3/4 and later 2/4. The main movements include a sliding step and hop. The écossaise was used as a musical form by Beethoven, Schubert, and Chopin. [29–1884–4]

ECOSYSTEM, a natural complex (biologically integral system) formed by living organisms (biocenosis) and their environment (abiotic, such as the atmosphere, or biotic, such as the soil and bodies of water), which are interrelated by the exchange of matter and energy. One of the basic concepts of ecology, it is applicable to objects of varying complexity and size.

One example of an ecosystem is a pond, with its plants, fish, invertebrates, microorganisms and bottom deposits and with the characteristic temperature fluctuations, quantity of oxygen dissolved in the water, the substances present in the water, and other factors with a specific biological productivity. Another example is a forest, with its litter, soil, microorganisms, birds, and herbivorous and predatory mammals and with the characteristic range of temperature, atmospheric humidity, light conditions, groundwaters, and other environmental factors and the characteristic exchange of matter and energy. A decaying stump in a forest, with the organisms living on and in it, together with their living conditions, may also be considered an ecosystem.

Ideally, an ecosystem in which the vital activities of autotrophic and heterotrophic organisms is in balance can approach the conditions of a closed system, which only exchanges energy with its surroundings. Under natural conditions, however, the continued existence of an ecosystem is possible only when there is a flow of both energy and a certain amount of matter from its surroundings. All existing ecosystems, which together make up the earth's biosphere, are of the open type, exchanging both matter and energy with their surroundings.

The term "ecosystem" is applicable to both natural and man-made ecosystems, such as agricultural land, gardens, and parks.

In the comprehensive study of natural complexes of interacting plants, animals, and microorganisms, scientists have assigned many different names to these supraorganismic units. Many of the terms have not gained wide usage, and some are used only in particular circumstances; for example, the term "biome" is used in the USA to designate such major ecosystems as the coniferous forest zone and the steppe zone.

The term "ecosystem," which has displaced many other terms of similar meaning, was proposed in 1935 by the British botanist A. Tansley. In 1944, V. N. Sukachev introduced the term biogeocenosis for terrestrial living systems, but he did not consider it to be synonymous with the term "ecosystem." Indeed, even aquariums and beehives are certainly examples of ecosystems, but they cannot be called biogeocenoses. Moreover, a general feature of a biogeocenosis is a smaller total animal biomass in comparison with the plant biomass, while in an aquatic ecosystem the opposite is true.

An ecosystem is distinguished by its species composition, the number of individuals of the various species, and the biomass, distribution, and seasonal dynamics of the species. Beginning in the 1940's and 1950's, research has been carried out that makes it possible to characterize quantitatively the functional features of an ecosystem (especially the food chains) by way of which the biological transformation of matter and energy proceed. The quantitative expression of the rate and efficiency of these processes by means of modern methods, and particularly by means of mathematical modeling of ecosystems, is an essential starting point for dealing with the urgent questions of the rational use of natural resources and the preservation of man's environment.

ECOSYSTEM, CLOSED, a functionally unified assemblage of organisms (plants, animals, and microorganisms) inhabiting a common territory and capable of prolonged existence under conditions of a closed cycle of matter (that is, in the absence of matter exchange across the boundaries).

The ecosystem principle is used in the development of life-support systems to maintain human life in places other than the earth's biosphere, for example, in spacecraft or underwater craft. Such an artificially created ecosystem is based on plants, which in the process of photosynthesis use light energy to absorb carbon dioxide and release oxygen, that is, regenerate the atmosphere. The plant biomass can be used as food by man and by other heterotrophic organisms, which themselves, in turn, can serve as food for man. The unused plant biomass and the metabolic wastes of man and other components of the artificial biocenosis are decomposed by microorganisms to form water, carbon dioxide, and mineral substances, which are reused by the plants.

Experimental closed ecosystems have been created in the USSR consisting of man, unicellular algae, higher plants (cabbages, carrots, beets, tomatoes, wheat), and microorganisms, which act as mineralizers. Regeneration in such ecosystems fully satisfies man's requirements for oxygen and water and provides 20 percent of his food. Natural ecolosystems usually are referred to simply as ecosystems.

ECOTYPE, a group of similar populations within one and the same plant species that are adapted to certain climatic, edaphic, or cenotic conditions and that have developed, under these conditions, hereditary morphological, physiological, biochemical, and other features. Thus, an ecotype is isolated with respect to distribution; genotypically it is an intraspecific subdivision, which distinguishes it from a biotype.

The term "ecotype" was introduced in the 1920's by the Swedish scientist G. Turesson. Different plants have different numbers of ecotypes. The ecotypic composition of a species becomes more varied as its geographic range and ecological amplitude increase. For example, 36 ecotypes have been distinguished in the pine *Pinus silvestris* and 27 in the spruce *Picea abies*. Ecotypic polymorphism is most clearly manifested at the center of speciation and morphogenesis. In the medic *Medicago falcata*, for example, there are many ecotypes in the Caucasus and only a few in the northern USSR. Parallel ecotypic differentiation is observed in many species. Thus, the wormwood *Artemisia campestris*, sheep sorrel (*Rumex acetosella*), and *Silene uniflora*, which grow in

bright, dry habitats where there are strong winds, develop ecotypes with procumbent stems.

Three main groups of ecotypes are distinguished: climatic, edaphic, and biotypic. Climatic, or geographic, ecotypes occupy a separate part of the area of distribution of a species and originated under the influence of specific climatic conditions; for example, in the awnless brome (*Bromus inermis*), the southern ecotype differs from the northern one by its nanism, narrow rough leaves, and wax coating. Edaphic ecotypes develop under the influence of soil and ground conditions, such as the pine ecotype on the chalky outcrops of the Don River, which has even been described as the independent species *Pinus cretacea*. Biotypic, or cenotic, ecotypes appear and develop mainly under the influence of plants together with which the given species form plant communities, for example, the field and forest ecotypes of the cocksfoot (*Dactylis glomerata*) and the forest and dune ecotypes of the narrow-leaved hawkweed (*Hieracium umbellatum*).

The development of an ecotype is a lengthy process. If an ecotype has progressive characteristics, which permit it to extend the range of the species, it may give rise to a new species, and consequently an ecotype is one of the stages in the process of speciation.

ECZEMA, an acute or chronic noncontagious inflammatory disease of the skin, neuroallergic in nature and characterized by various eruptions, a burning sensation, itching, and a tendency to recur. A variety of factors, both external (mechanical, chemical, thermal) and internal (diseases of the liver, kidneys, gastrointestinal tract, endocrine and nervous systems), are conducive to the development of eczema.

Several forms of eczema are distinguished, depending on the cause, site, and nature of the inflammation. True eczema is marked by a sudden onset; multiple sites of inflammation, including the nails; symmetrical location of the foci, which have indistinct contours; and reddening of the skin in the affected area. Other symptoms are the formation of minute blisters, some of which change into pustules or moist spots (hence the obsolete name "weeping lichen"), and later the formation of scales and crusts.

In microbial eczema (perivulnus), the foci are usually arranged asymmetrically, mainly on the upper and lower limbs, and have sharp, irregular contours. The skin near the lesions is bluish red and thickened and has pustular and other eruptions and purulent and bloody crusts. Reddening of the skin, edema, numerous blisters, nodules, pustules, and weeping spots occur, mainly on the palms, soles, and fingers.

Seborrheic eczema, or dermatitis seborrheica, is localized mainly on the scalp, forehead, and chest, behind the ears, around the nose and lips, in the armpits, in the groin, and around the umbilicus. The scalp is red and dry, with many grayish scales and seropurulent crusts on a moist surface. Reddening, edema, and weeping are quite pronounced, and there may be painful cracks. The trunk has clearly yellowish pink desquamative spots, some with tiny nodules in the center.

Treatment, depending on the cause and form of the eczema, includes the use of sedatives (valerian, tranquilizers), vitamins (B_1, B_6, C), and desensitizing and other agents. Also advisable are special diets, treatment in health resorts, and the local application of lotions, pastes, ointments, and antipruritic agents.

EDDINGTON, ARTHUR STANLEY. Born Dec. 28, 1882, in Kendal, Westmorland; died Nov. 22, 1944, in Cambridge. British astronomer. Fellow of the Royal Society of London (1914).

From 1906 to 1913, Eddington was on the staff of the Royal Observatory at Greenwich. He was appointed a professor at Cambridge University in 1913 and became the director of the astronomical observatory at Cambridge in 1914. From 1921 to 1923 he was the president of the Royal Astronomical Society in London.

Eddington's works dealt mainly with stellar motions, the internal structure of stars, the theory of relativity, and relativistic cosmology. Eddington was the first to apply the theory of radiative equilibrium to stellar interiors; he developed the theory of a gaseous star in radiative equilibrium. He discovered the relationship between the luminosity and the mass of a star and was the first to calculate models of stars in radiative equilibrium.

Eddington was a member of several foreign academies and scientific societies.

EDE, a city in Nigeria, in the state of Oyo; situated on the upper Oshun River. Population, 182,000 (1975). Ede is the center of a region producing cacao beans. Cacao beans, tobacco, and cotton are traded and agricultural raw materials are processed in the city. [29–1679–2]

EDE, a city in the Netherlands, in the province of Gelderland. Population, 79,900 (1975). Ede is a railroad junction. Industrial enterprises include a branch of the AKZO chemical-fiber concern and plants for the manufacture of textiles, tobacco and food products, metal articles, and pianos. [29–1679–3]

EDÉA, a city in Cameroon, on the left bank of the Sanaga River, in Coastal Province. Population, 23,000 (1970). A trade and transportation center, Edéa is connected by railroad and highway with the city of Yaoundé and the port of Douala. It has a hydroelectric power plant with a capacity of 264 megawatts (1976) on the Sanaga River. An aluminum plant in the city uses electricity from the hydroelectric plant and alumina imported from the Republic of Guinea. Other industries in Edéa include palm oil production and woodworking. [29–1679–4]

EDELFELT, ALBERT. Born July 21, 1854, near Borgå; died Aug. 18, 1905, in Borgå. Finnish painter.

Edelfelt studied at the School of Drawing of the Society for the Encouragement of Artists in Helsingfors under B. Lindholm and B. Reinhold (1868–71), at the Antwerp Academy of Sciences (1873–74), and in Paris under J. L. Gérôme (1874).

Edelfelt, a representative of the realist school, was also influenced by impressionism. His works include historical scenes (*The Swedish King Charles Mutilates the Corpse of His Enemy Stadtholder Flemming in 1537*, 1878) and scenes from the life of the people (*Peasant Women From Ruokolahti*, 1887; *Fishermen From Distant Islands*, 1898), as well as landscapes and portraits (*Mother*, 1883; *Louis Pasteur*, 1885; *A. Ackté*, 1901). Edelfelt's works are noted for their free, expressive use of form, subtle rendering of light and air, and bright, festive colors. All works mentioned are housed in the Atheneum in Helsinki.

EDELMAN, GERALD MAURICE. Born July 1, 1929, in New York. American biochemist. Member of the American Academy of Arts and Sciences and the New York Academy of Sciences.

Edelman graduated from Ursinus College in 1950, and he received his M.D. in 1954. In 1957 he joined the staff of the Rockefeller Institute of Medical Research, and he became a professor there in 1966. Edelman's research has dealt mainly with the primary and tertiary structure of proteins, especially antibodies (immunoglobulins), and with the structure of the cell surface. He applied new methods for the fractionation of antibodies and cells, and he developed a method of fluorescence spectroscopy for proteins. Edelman discovered that the gamma globulin molecule consists of four polypeptide chains.

Together with R. R. Porter, Edelman was awarded a Nobel Prize in 1972. [29–1680–1]

EDEL'SHTEIN, VITALII IVANOVICH. Born Apr. 17 (29), 1881, in Kazan; died Aug. 1, 1965, in Moscow. Soviet scientist, specialist in vegetable cultivation. Honorary member of the V. I. Lenin All-Union Academy of Agricultural Sciences (1956). Hero of Socialist Labor (1961). Member of the CPSU from 1952.

Edel'shtein graduated from the St. Petersburg Forestry Institute in 1902 and worked in the institute's department of botany until 1907. He taught at the Uman' Agricultural School from 1907 to 1913 and later became head of the Tula Fruit and Vegetable Station. In 1916 he became a professor in the department of fruit and vegetable growing of the Moscow Agricultural Institute (now the K. A. Timiriazev Moscow Agricultural Academy). Edel'shtein's principal works deal with the biology of vegetables, vegetable-growing techniques, and methods of obtaining seedlings. They include the textbook *Vegetable Growing* (1944; State Prize, 1946).

Edel'shtein was awarded two Orders of Lenin, the Order of the Badge of Honor, and several medals.

EDÉN, NILS. Born Aug. 25, 1871, in Piteå; died June 16, 1945, in Stockholm. Swedish political figure and historian. Doctor of sciences (1899).

Edén studied at the University of Uppsala and was a professor at the university from 1903 to 1920. In 1905, at the behest of the government, he developed a program to resolve the crisis in the Swedish-Norwegian Union, which had been formed in 1814.

Edén was a member of the Riksdag from 1909 to 1924. He led the Liberal Coalition Party of Sweden from 1918 to 1923, and from 1917 to 1920 he served as prime minister of a coalition government, which carried out a number of bourgeois democratic reforms. After his party split in 1923, he ceased to play an active role in politics.

Edén's principal works deal with the Swedish-Norwegian Union, the organization of the Swedish central administration in the 16th and 17th centuries, and 17th-century foreign policy. Edén was responsible for the publication of much valuable source material.

EDER, BORIS AFANAS'EVICH. Born July 12 (24), 1894, in Batumi; died Nov. 15, 1970, in Moscow. Soviet circus performer. People's Artist of the RSFSR (1939). Member of the CPSU from 1954.

From the time he first entered the circus ring in 1908, Eder appeared as a gymnast, acrobat, and high-wire artist. He created and performed in the special aerial gymnastic act "Airplane Flight Around the Eiffel Tower." In 1932, Eder gained prominence as an animal trainer; he worked with many different animals, including lions, brown bears, polar bears, tigers, elephants, and ostriches. An advocate of humane methods of training, Eder used affection, encouragement, and precise command gestures and voice inflections. Eder's students include M. P. Nazarova, V. M. Zapashnyi, and E. M. Podchernikova. Eder also served as a consultant for several films, including *Dangerous Trails*, *The Lady Tiger Tamer* and *Don Quixote*.

EDFU (present-day Idfu), an ancient city in Upper Egypt, in what is now the *muhafazah* (governorate) of Aswan; situated on the left bank of the Nile. From predynastic times, Edfu was the center of the cult of the sun-god, who was depicted as a winged disk. Later this god was identified with Horus and then with Apollo, and as a result the city was known as Apollonopolis Magna in Greco-Roman times.

Preserved structures include a temple complex devoted to the worship of Horus; the complex, which dates from Ptolemaic times (237 B.C. to the mid-first century B.C.), was built on the site of an ancient temple of the time of Ramses III. Excavations conducted in the 1920's and 1930's yielded residential quarters of the city and a necropolis. Articles of everyday use have been found, some from the period of the Old Kingdom but mainly from the Greco-Roman, Coptic, and Byzantine periods.

EDGE ISLAND, an island in the southwestern part of the Spitzbergen Archipelago. Edge Island, a possession of Norway, covers an area of 5,030 sq km. It is composed primarily of sandstones and shales. The maximum elevation is 716 m. The area of glaciation is 1,880 sq km; the ice cover is not solid, and the Stone and King Johan glaciers, among others, flow into the valleys. The vegetation features arctic wasteland and tundra, consisting of mosses, lichens, and other plants. The island was discovered in 1613 by the English navigator T. Edge, although it had probably been discovered earlier by Russian seafarers. There are no permanent residents on the island. [29–1681–3]

EDGER, in a rolling mill, a roll stand having vertical rolls, designed to compress the metal being rolled along its side surfaces. The design and location of an edger depend on the type of rolling mill. In sheet and slabbing mills, edgers are used to produce smooth, even edges on the sheets and slabs; they have driven rolls and are situated either ahead or behind the main stand with horizontal rolls. The edgers of billet and section mills are designed to eliminate canting and distortion of the metal during rolling; they usually have driven rolls and are situated in alternation between stands having horizontal rolls. The edger rolls of rail and beam mills are situated in the same plane as the horizontal rolls and are designed without drives. Roll stands with both horizontal and vertical rolls are known as universal stands.

[29–1682–3]

EDGEWORTH, FRANCIS YSIDRO. Born Feb. 8, 1845, in Edgeworthstown, County Longford, Ireland; died Feb. 13, 1926, in Oxford. British economist and statistician; representative of the mathematical school of bourgeois political economy.

Edgeworth graduated from Oxford University in 1869. He was a professor of political economy at King's College in London from 1888 to 1891 and at Oxford from 1891 to 1922. He was president of the Royal Statistical Society from 1912 to 1914. Edge-

worth's theoretical views were greatly influenced by W. S. Jevons and A. Marshall. Edgeworth believed in the importance of the use of mathematics in economics. In his philosophical views he was an adherent of English utilitarianism. He was one of the first to introduce the concept of indifference curves into economics. He believed that the curves illustrated the selection by a consumer of the utility of different types of wealth. Edgeworth investigated the logical and philosophical foundations of probability and the possibility of measuring utility. He worked on a mathematical definition of economic equilibrium and on indexes. He emphasized the significance of functional analysis in investigating the relationships between individual elements of an economic system, rejecting the need to analyze cause-and-effect relationships between economic phenomena. Although Edgeworth published a significant number of works, he did not advance a unified and consistent theory. Individual positions developed by him were further developed by other Western economists.

EDGEWORTH, MARIA. Born Jan. 1, 1767, in Black Bourton, Great Britain; died May 22, 1849, in Edgeworthstown, Ireland. Irish writer.

In *Letters to Literary Ladies* (1795) and *Practical Education* (vols. 1–2, 1798), Edgeworth presented a detailed program of education, including that of women, in the spirit of the pedagogical ideas of the Enlightenment. A profound penetration into child psychology can be observed in her didactic stories for children. Edgeworth gained fame for her "Irish novels." The destruction of the patriarchal way of life and the triumph of bourgeois relationships are the subject matter of the novel of society and everyday life *Castle Rackrent* (1800; Russian translation, 1972). The novel *The Absentee* (1812; Russian translation, 1972) is devoted to the urgent problems of early 19th-century Ireland. In laying bare class haughtiness and affectation, Edgeworth proved herself to be an outstanding satirist. Her realistic mastery comes to life most brilliantly in her portraits of heroes from among the people. She was the author of the novels *Belinda* (1801) and *Tales of Fashionable Life* (series 1–2, 1809–12). Edgeworth's pedagogical essays and stories for children were popular in Russia.

EDICT. (1) In Roman law, an authoritative order or statement issued by a magistrate, especially a praetor, upon assumption of office to present his program. The edict remained in force throughout the magistrate's term. In practice, the basic legal provisions of the praetorian edict were recopied from year to year and thus took on a general normative character. In the second century A.D., the Roman jurist Salvius Julianus drew up the final text of the praetorian edict.

(2) In the Roman Empire and a number of the medieval monarchies of Western Europe, a type of law issued by the emperor or sovereign. An example of such an edict is the Edict of Nantes, which was issued in 1598 in France. [29–1683–5]

EDIFICATOR, a plant species having a clearly defined habitat-formation ability, that is, the ability to determine the structure and, to a certain extent, the species composition of a plant community, or phytocoenosis. Edificators have a great effect on the environment and, through it, on the lives of the other plants in the community. An example is the fir, whose dense crown retains as much as 50 percent of the precipitation and allows little light to filter through. As a result, it is always dark in a dense fir forest, and only shade-tolerant vegetation can live there. In addition, there is an increased content of watery vapors and carbon dioxide under the foliage canopy of fir trees. The temperature drops during the day and rises at night (in comparison with neighboring open spaces), thereby affecting the average annual temperature within the forest. Edificators are of great importance within the system of phytocoenotypes. [29–1687–1]

EDIL'BAEV SHEEP, a breed of fat-tailed, coarse-wooled sheep raised for meat and tallow. The Edil'baev sheep was developed in the late 19th century by Kazakh herdsmen, who crossed Kazakh fat-tailed sheep with Astrakhan coarse-wooled rams. Subsequently those animals that were best adapted to the natural and climatic conditions of nomadic sheep raising were selected.

Both rams and ewes are polled. The rams weigh 100–120 kg, sometimes as much as 160 kg; the ewes weigh 65–75 kg, sometimes as much as 115 kg. The sheep grow rapidly and mature early. The yield of meat is 50–55 percent. The wool is predominantly rufous, brown, and black, occasionally white or gray. The fleece measures approximately 15 cm in length; the yield of wool from two clippings is 3.5 kg from rams and 2.3–2.6 kg from ewes. Fertility is 110–120 lambs per 100 ewes. The sheep are bred principally in the Kazakh SSR.

EDINBURGH a city and royal burgh in Great Britain; capital of Scotland and center of the province of Lothian. Population, 543,000 (1971). Edinburgh is situated near the Firth of Forth, an inlet of the North Sea; the port of Leith on the shore of the firth is within the city limits. Edinburgh is a transportation junction and an industrial center, as well as an important cultural center. It has enterprises of the printing, paper, pharmaceutical, and food-processing industries. Machinery is also produced, including electrical equipment and machinery for the paper industry. The city is the home of the Royal Scottish Academy, and it has a university.

The first written information about Edinburgh dates from the sixth century. Edinburgh probably received the rights of a city in the 12th century. It became the capital of Scotland in the mid-15th century. From the 13th to the 17th centuries it was repeatedly occupied by English troops, which caused considerable destruction. The city's importance as a political and administrative center declined in the 17th and 18th centuries as a result of the union of Scotland and England. During the industrial revolution, which began in the mid-18th century, the city's commercial, industrial, and financial role increased. In the 1830's a trade union council was founded in Edinburgh and the Chartist movement spread.

Edinburgh, one of Europe's most beautiful cities, is known as the Athens of the North. It is situated on several hills and has narrow, winding streets lined with towerlike houses, up to 12 stories high, of coarse stone. The new part has a regular layout (plan of 1767–68, architect J. Craig) with beautifully integrated architecture in the classical style. Notable structures include the former royal castle (11th–16th centuries) and Holyrood Palace, residence of the Scottish kings (begun 1128). Also of interest are the city's 16th-century houses, classical-style buildings and architectural complexes, including Charlotte Square (1792–1807, architect R. Adam and others), and neo-Gothic structures. The Turnhouse air terminal was built in 1955 by R. Matthew. Museums include the Royal Scottish Museum, the National Museum of Antiquities of Scotland, and the National Gallery of Scotland.

EDINBURGH, UNIVERSITY OF, the largest higher educational institution in Scotland. The university was founded in 1583. In 1976 it had faculties of divinity, law, arts, social sciences, science, medicine, veterinary medicine, and music. Attached institutions include the New College (founded 1846), an institute of humanities, and a center of rural economy. The university has more than 11,000 students, and the teaching staff numbers 1,370. The university library, founded in 1580, has more than 1 million volumes. [29–1685–1]

EDIRNE, a city in northwestern Turkey; situated in the valley of the Maritsa River, in Eastern Thrace. Administrative center of Edirne Vilayet. Population, 63,000 (1975).

Edirne, an important transportation junction on the border with Bulgaria and Greece, is situated on the Istanbul-Sofia rail line and is a highway junction. It is the trade center of an agricultural region producing grains and oil-yielding seed. Edirne has flour and vegetable-oil mills and a cotton-textile factory.

Edirne is thought to have been founded by the ancient Thracians, who called it Odrys. From the fourth to the mid-second century B.C. it was a colony of Macedonia and was called Orestia. The city came under Roman rule in the second half of the second century B.C. In A.D. 125 it was rebuilt by the Roman emperor Hadrian and named Hadrianopolis (Adrianople) in his honor. From the late fourth to the mid-14th centuries it was part of Byzantium, except for the period 1204–61, when it was part of the Latin Empire. In the early 1360's it was conquered by the Ottoman Turks and named Edirne. It was the capital of the Ottoman Empire until 1453.

Ancient Edirne, which had a regular layout, was situated in the southwestern part of the present-day city. To the northeast there is a medieval Muslim city, with radial streets. Architectural monuments include several notable mosques, for example, Eski Cami (1403–13), Uç Şerefeli (1437–47), and Selimiye Cami (1569–75, architect Sinan). [29–1686–2]

EDISON, THOMAS ALVA. Born Feb. 11, 1847, in Milan, Ohio; died Oct. 18, 1931, in West Orange, N.J. American inventor in electrical engineering, the owner and founder of major electrical engineering companies.

Edison was a descendant of Dutch immigrants. After receiving a primary education, he began working at the age of 12 as a newsboy and later as a telegraph operator. Having made his home in Newark, N.J., he produced his first invention in 1868 and opened a workshop where his devices were manufactured. Between 1869 and 1876, Edison designed a number of original devices, including the stock ticker. He also worked on multiplex telegraphy and improved the typewriter.

In 1876, Edison moved to Menlo Park, N.J., where he resided until 1887. At Menlo Park, he established a major laboratory with workshops. During this period, he improved A. Bell's telephone and, in 1877, invented the phonograph. In 1879 he proposed and introduced a commercially practical incandescent lamp. He also invented various electrical devices, such as the screw socket and base for electric lamps, the electric fuse, a rotary switch, and the electric meter. In addition, Edison carried out experiments on the electrification of railroads and developed a magnetic method of ore separation. In 1883 he discovered thermionic emission, which is known as the Edison effect. Edison also designed electric generators that were the most powerful of their day. In 1882 the world's first DC electric power plant designed to provide power to the public was built in New York City according to his specifications.

In the late 1880's, Edison established a number of major concerns for the production and sale of electric machines and equipment, lighting equipment, and incandescent lamps. His concerns also operated the electric power plants and telegraph stations that he had built in the USA and Europe.

From 1887 until his death, Edison resided in West Orange, N.J., where he headed his "invention factory." During this period, he improved the phonograph and the motion-picture camera. He also invented a device that was the prototype of the dictating machine, equipment for recording telephone conversations, a railroad brake, and the nickel-iron battery.

G. K. TSVERAVA [29–1686–3]

EDITORIAL TECHNIQUE, methods used in the publication of scholarly texts, primarily well-established ones, such as classical works, historical or linguistic sources, and documents; one of the applied uses of textual criticism.

The most important task in editorial technique is the establishment of a text for publication through studying its history. An established text must correspond to the creative intentions of the writer and be free of extraneous additions and damage, in particular, changes linked with censorship (including self-censorship). Another task is the transcription of the text, which involves applying modern orthography and script while preserving the essence of the content, as well as lexicological, morphological, syntactical, and phonetic peculiarities of the published text. Of utmost importance is the formulation of a reference apparatus, including accompanying articles, indexes, and especially commentaries (notes).

The resolution of all the problems of editorial technique depends on whether the publication is intended to be scholarly or popular. In regard to structure and content, the text may be published as a complete collection of works, selected works, an anthology, or a publication of separate works or documents.

Specialists in editorial technique and textual criticism cannot merely rely on the mechanical application of previously established "rules." Universal conventions do not take into account all the various forms, shades of meaning, and unusual connotations of the written word. Certain rules, such as those set by the latest text, are justified in most cases; however, they do not relieve the scholar of his duty to undertake concrete research to establish the authentic creative intentions of the author. A philological analysis of the text necessitates the collation of sources to make known the latest interpretations; various techniques of scholarly philological research are also indispensable. An established text is not declared the standard one, but is acknowledged as such (at the current level of study) by a number of authorities. The work of the editor is documented and substantiated within the publication and therefore can be checked by the reader.

See under TEXTUAL CRITICISM.

A. L. GRISHUNIN [29–1687–2]

EDJELEH, a settlement in Algeria, in the northeastern part of the Sahara, near the Algerian-Libyan border. Edjeleh is the center of the Edjeleh petroleum-producing basin, which consists of the Edjeleh, Tiguentourine, and Zarzaitin fields, opened between 1956 and 1958. Approximately 10 million tons of petroleum are extracted from the basin annually. The oil is pumped from the basin to the Mediterranean port of Cekhira, Tunisia. [29–1682–1]

EDMONTON, a city in western Canada, on the North Saskatchewan River. Capital of the province of Alberta. Population, 518,000 (1973; including suburbs). Edmonton is an important center for transportation, commercial distribution, industry, finance, and culture in western Canada. Oil refining and and petroleum chemistry are important industries. Enterprises include a pipe-rolling mill, a plant for the production of oil-drilling equipment, and factories for the processing of agricultural raw material. The city has a university. [29–1688–1]

EDOM (Greek, Idumaea), an ancient country in Southwest Asia, south of Palestine, between the Dead Sea and the Gulf of Aqaba; named for the Edomites.

In the second half of the second millennium B.C., the land was settled by the Edomites, who united to form a state in the late second millennium B.C. In the 11th century B.C., Edom was subjugated by the tribes of Israel. It paid a tribute to Assyria from the ninth to seventh centuries and to the neo-Babylonian kingdom in

the seventh and sixth centuries. Together with the Babylonians, the Edomites laid seige to Jerusalem in 586 B.C. and destroyed the city. By the late sixth century they governed part of southern Palestine.

When the Nabataean kingdom was formed in the late third century B.C., much of Edom was incorporated into it. With part of southern Palestine (capital, Hebron), western Edom became the independent kingdom of Idumaea. In the late second century B.C., Idumaea was conquered by a Judean king of the Hasmonean dynasty, and the population was converted to Judaism.

Together with Judea, Idumaea was subjugated by Rome in 63 B.C. and became a Roman protectorate. King Herod I was an Idumaean. In 106 A.D., a large part of Idumaea was incorporated into the Roman province of Arabia. [29–1688–4]

EDRIOASTEROIDEA, a class of extinct marine Paleozoic animals of the phylum Echinodermata. The theca resembled a pouch or disk and lacked a stalk, arms, and brachioles. Most Edrioasteroidea attached themselves to a substrate, although some lay freely on the bottom. Particles of food entered the oral field along the ambulacral grooves, through the pores of which the tube feet of the abulacral system emerged.

The Edrioasteroidea lived from the Cambrian to the Carboniferous, flourishing in the Middle Ordovician and Late Devonian. Remains are seldom found. About 30 genera with 100 species are known, almost all from Europe and North America. In the USSR they have been found in Ordovician deposits in Estonia and in Devonian deposits in Leningrad and Voronezh oblasts of the RSFSR.

EDWARD. In England:

Edward I. Born June 17, 1239, in London; died July 7, 1307, near Carlisle. King from 1272. Member of the Plantagenet dynasty.

During the reign of Edward I, the estate monarchy took shape in England as the regular convocation of Parliament became an established practice. In his domestic policy Edward I strove to maintain the equilibrium that had arisen within the class of feudal lords as a result of the civil war of the 1260's and sought to strengthen the alliance of the royal power with the knights and the cities; at the same time he waged a cautious offensive against the secular and clerical aristocracy, especially through the Statutes of Westminster. Because of the great dissatisfaction with rising taxes felt by the knights and the burghers, who were supported by the barons, Edward I was forced in 1297 to recognize officially Parliament's right to sanction state taxes. Under his rule, Wales was forcibly annexed by England between 1282 and 1284. Edward I attempted to conquer Scotland beginning in 1286, but his efforts met with the stubborn resistance of the Scottish people.

Edward III. Born Nov. 13, 1312, in Windsor; died June 21, 1377, in Sheen, now Richmond. King from 1327. Member of the Plantagenet dynasty.

Edward III ruled independently from 1330. A grandson of the French king Philip IV the Fair on his mother's side, Edward III took advantage of the extinction of the Capetian dynasty in France to lay claim to the French throne; he declared war on France in 1337, thereby beginning the Hundred Years' War (1337–1453). After the plague of 1348 (the Black Death), which gave rise to a lack of manpower and to an increase in wages, Edward III promulgated several laws in the interests of the feudal lords that compelled laborers to work at pay rates that had existed before the plague. In an attempt to subordinate the English church to the royal power, he prohibited in 1353 the transfer of cases involving English subjects to the papal curia, and he refused to provide certain traditional cash payments to the pope. In 1371, the decrepit king virtually handed over the conduct of state affairs to his son John of Gaunt.

Edward IV. Born Apr. 28, 1442, in Rouen; died Apr. 9, 1483, in London. King from 1461 to 1483, with an interruption from October 1470 to April 1471. First king of the York dynasty.

Edward IV seized the throne during the Wars of the Roses by deposing Henry VI of Lancaster. His attempts to reduce the political power of the feudal aristocracy led his followers among the barons, headed by the Earl of Warwick, to join the Lancastrians. Edward IV was deposed in October 1470. He regained the throne in April 1471 by defeating the Lancastrians at Barnet; in May 1471 he defeated them again at Tewkesbury. The stability of the royal treasury, which was formed from "voluntary" gifts by the population, compulsory loans from cities, and customs duties, enabled Edward IV generally to rule without convoking Parliament. Edward IV enacted measures promoting English industry, especially cloth manufacture, and trade.

Edward VI. Born Oct. 12, 1537, in Hampton Court; died July 6, 1553, in Greenwich. King from 1547. Member of the Tudor dynasty.

Because of his youth and ill health, Edward VI played virtually no role in the conduct of state affairs.

Edward VII. Born Nov. 9, 1841, in London; died May 5, 1910, in Windsor. King from 1901. First king of the Saxe-Coburg-Gotha dynasty (Windsor dynasty since 1917).

Edward VII took part in the formation of the Entente. At a meeting with the Austro-Hungarian emperor Francis Joseph in 1907, he tried unsuccessfully to make Austria-Hungary break its alliance with Germany. Edward VII did not play a significant role in domestic policy.

Edward VIII. Born June 23, 1894, in Richmond; died May 28, 1972, in Paris. King from January to December 1936.

Edward VIII's attempts to take part in political affairs and his intention to enter into a marriage that was contrary to the traditions of dynastic marriage caused sharp dissatisfaction among certain elements in the ruling circles of Great Britain. A palace crisis ensued, and he abdicated in favor of his younger brother, who became King George VI. On his abdication, Edward VIII was given the title of duke of Windsor. During World War II he was governor of the Bahamas. Edward spent the last years of his life in France. [29–1690–2]

EDWARD (THE BLACK PRINCE). Born June 15, 1330, in Woodstock; died June 8, 1376, in London. Eldest son of the English king Edward III; prince of Wales. Nicknamed the Black Prince probably because of his black armor.

Edward was one of the principal English military commanders in the first phase of the Hundred Years' War of 1337–1453. He gained particular renown as a result of English victories at the battle of Crécy in 1346 and the battle of Poitiers in 1356. In 1362 he became ruler of the French province of Aquitaine, which had been conquered by the English. The levying of taxes and acts of plunder and violence by English troops in the province gave rise to determined resistance on the part of the local population, and Edward was compelled to return to England in 1371. [29–308–4]

EDWARD, a lake in East Africa, in the Nile basin, on the border between Zaïre and Uganda. Lake Edward became known as Lake Idi Amin Dada in 1973. The lake has an area of 2,150 sq km and a maximum depth of 111 m. It is located in a tectonic basin at an elevation of 912 m. The Semliki River flows out of Lake Edward and empties into Lake Albert (Lake Mobutu Sese Seko). Lake Edward is fished commercially. [29–1691–1]

EDWARD VII PENINSULA, the northwestern extremity of Marie Byrd Land, in Western Antarctica. On the south, Edward VII Peninsula adjoins the Ross Ice Shelf. It is covered with an ice sheet that is nearly 500 m thick; above the surface of the ice rise mountain ranges, such as the Rockefeller and Alexandra mountains, and individual peaks, such as La Gorce Peak (elevation, 829 m). The peninsula was discovered in 1842 by a British expedition led by J. Ross; it was named Edward VII Land in honor of the British king. Its peninsula nature was established in 1929 by an American expedition led by R. Byrd. [29–1691–3]

EDWARDS, JONATHAN. Born Oct. 5, 1703, in East Windsor, Conn.; died Mar. 22, 1758, in Princeton, N.J. American religious

philosopher and Calvinist theologian; an opponent of atheism and materialism.

Edwards combined the mysticism of the Cambridge Platonists with views close to those of G. Berkeley and N. de Malebranche. For Edwards, god was the only reality and the cause of all that occurs. At the same time, he differed on a number of points from orthodox Calvinism. Edwards' ideas were sharply criticized by members of the American Enlightenment.

EDWARDS PLATEAU, a plateau in the southern United States, in the state of Texas, between the valleys of the Columbia River and the Rio Grande. The plateau, which has an elevation of 700–800 m, constitutes part of the Great Plains. It is deeply dissected by canyon-like river valleys. Dry prairie grasses, succulents, and mesquite are the principal forms of vegetation. Livestock graze on the Edwards Plateau. [29–1692–2]

EDWARD THE CONFESSOR. Born circa 1003, in Islip, Oxfordshire; died Jan. 5, 1066, in London. Anglo-Saxon king from 1042.

Edward was chosen king by a council of the nobility, who sought through him to restore the ancient Anglo-Saxon dynasty and end the Danish domination of England. He left the Continent, where he had lived for many years, and returned to England accompanied by a large entourage of Norman feudal lords, who soon occupied key positions at his court. Dissatisfaction with Norman dominance resulted in an uprising in 1051. Led by Godwin of Wessex, Edward's father-in-law, the rebels achieved the expulsion of the Normans from England. The administration of the state passed first to Godwin, who died in 1053, and then to Godwin's son Harold, whom Edward named as his successor to the throne. [29–1691–2]

EEDEN, FREDERIK VAN. Born Apr. 3, 1860, in Haarlem; died June 16, 1932, in Bussum. Dutch writer.

Eeden, one of the "men of the eighties," was a founder and editor of the journal *De nieuwe gids*. His most significant work is his *Little Johannes* (also known as *The Quest*; parts 1–3, 1887–1906; Russian translation, 1914). Eeden's enthusiasm for Christian socialism was reflected in the plays *The Brothers* (1894) and *Lioba* (1897); however, the play *The Promised Land* expresses disenchantment with social reconstruction. Eeden's enthusiasm for Catholicism is reflected in his collection *To My Guardian Angel and Other Poems*.

EEKHOUD, GEORGES. Born May 27, 1854, in Antwerp; died May 28, 1927, in Brussels. Belgian writer who wrote in French.

Eekhoud, a member of La Jeune Belgique, was one of Belgium's first novelists. At first a regionalist writer, he was the author of the novel *Kees Doorik* (1883) and the short-story collection *Country Fair* (1884). The novel *The New Carthage* (1888) offered a highly original, typically Belgian portrayal of the "octopus city." The novel *The Libertines of Antwerp* (1912) expressed utopian ideas of the "emancipation of the flesh" and deified nature.

EEMIAN INTERGLACIAL (from Eems, the Dutch name for the Ems River of the North Sea basin), the interglacial that separates the Saale (Riss) glacial from the Vistula (Würm) glacial in Western Europe. The Eemian interglacial occurred 120,000–130,000 years ago; it corresponds to the Mikulino interglacial in the European part of the USSR [*see* ANTHROPOGENIC SYSTEM (PERIOD)]. [29–1693–1]

EGADI ISLANDS, a group of Italian islands in the Mediterranean Sea, west of Sicily. Area, about 40 sq km. Population, 6,100 (1968). The islands are composed mainly of limestones. They are characterized by hills and low mountains, which rise to an elevation of 686 m on the island of Marettimo. The islands contain citrus plantations and vineyards; there is fishing for tuna. [29–1669–5]

EGALITARIANISM, a petit bourgeois utopian philosophy advocating universal leveling as the organizing principle of society.

In its earliest forms, in classical times and the Middle Ages, egalitarianism was associated with a demand for equal redistribution of the land. Under early capitalism two basic trends developed within egalitarianism. The first advocated equalization of the property of individual producers; the institution of private property was to be retained. The Jacobin dictatorship attempted to put into practice this ideal, which derived from the teachings of J.-J. Rousseau. The second trend in egalitarianism was associated with the earliest communist utopian groups, such as the Babouvists; it advocated equal distribution of labor and goods on the basis of communal property.

K. Marx and F. Engels considered the principles of universal asceticism and crude leveling, which were characteristic of early communist literature, to be reactionary elements (see *Soch.*, 2nd ed., vol. 4, p. 455). The reactionary features of egalitarianism found particularly vivid expression in "barracks communism," which reduced people's capabilities and needs to one level. Under conditions in which the proletariat has not yet taken shape as a class, the advancement of the principle of egalitarianism against the exploiting classes is, as Engels said, "a necessary stage of transition" from plebeian and petit bourgeois revolutionism to proletarian revolutionism (*ibid.*, vol. 7, p. 377). In modern times, however, egalitarianism is a reactionary principle that is in opposition to the revolutionary ideals and the principle of equality advanced by the working class. E. G. PANFILOV [29–1670–1]

EGBA UPRISING, a major revolt of the Africans in Nigeria against the British colonial authorities and their network of agents. The uprising, which was provoked by the colonial authorities' introduction of direct taxation, took place in June 1918 in the small state of the Egba in western Nigeria. During the uprising, the Egba seized several administrative buildings, demolished storage facilities, and severed the railroad and telegraph lines that linked the cities of Baro and Minna. The local ruler, or *alake*, was forced to flee. The colonial authorities sent an army unit of approximately 1,000 officers and men to suppress the revolt. The rebels lost more than 3,500 men during the uprising. [29–1670–2]

EGBERT (also Ecgberht, Ecgbryht). Died 839. King of the Anglo-Saxon state of Wessex from 802.

Egbert united the feuding Anglo-Saxon kingdoms under his rule by annexing Cornwall, Kent, Essex, Sussex, Mercia, and Northumbria. [29–1670–4]

EGEDE-NISSEN, ADAM HJALMAR. Born June 29, 1868, near Christiania (now Oslo); died there Apr. 4, 1953. Figure in the Norwegian working-class and communist movement. Nephew of O. Egede-Nissen, a follower of Garibaldi.

A postal worker by profession, A. H. Egede-Nissen was a member of the Storting from 1900 to 1912 and again from 1922 to 1924. In the early 1900's, he helped the Russian Social Democrats print revolutionary literature in Vardö and deliver it to Russia. In January 1918 he visited Soviet Russia and met with V. I. Lenin. Egede-Nissen was a member of the Norwegian Labor Party from 1906 to 1923, when he joined the Communist Party of Norway (CPN). In 1935 he was a delegate to the Seventh Congress of the Comintern, and from 1933 to 1935 he served as chairman of the Society of Friends of the Soviet Union. Egede-Nissen was chairman of the CPN from 1934 to 1940 and in 1945 and 1946. In 1946 he was named an honored member of the CPN.

Egede-Nissen was the author of the memoirs *With Lenin Twenty Years Ago* (1937) and *Life in the Struggle* (1945).

[29–1671–1]

EGER, a city in northern Hungary, on the Eger River. Situated near the southern foot of the Bükk Mountains. Administrative center of the *megye* (county) of Heves. Population, 56,000 (1976). Eger produces engineering equipment, metal products, tobacco, furniture, milk, and wine. The city has a balneological health resort. Notable buildings in Eger, which has retained its medieval layout, include a 13th-century castle with fortifications dating from the 16th century, the Episcopal Palace (15th century), a Turkish minaret (1596–1687), the baroque County Council Hall (1751–55, architect M. Gerl), the Minorite Church (1758–73, architect Gerl), the *lycée* (1765–85, architect J. Fellner), and a cathedral in the classical style (1831–37, architect, J. Hild). The I. Dobi Museum has exhibits of archaeological remains and paintings, mainly Hungarian.

EGGERT, JOHN EMIL MAX. Born Aug. 1, 1891, in Berlin; died Sept. 29, 1973, in Zürich. German physical chemist.

A student of W. Nernst's, Eggert studied from 1909 to 1913 at the University of Berlin and the Technische Hochschule of Berlin. In 1913 he became a lecturer at the University of Berlin, and from 1923 to 1937 he was a professor there. From 1928 to 1945 he was head of the scientific laboratory of AGFA, and from 1946 to 1961 he was a professor at the Swiss Federal Institute of Technology in Zürich.

Eggert's main work dealt with the chemistry of photographic processes. He studied the photosensitivity of silver halides and determined the quantum yield of photochemical reactions in the halide crystals in emulsion layers. Eggert showed that the optical density of developed emulsion layers is dependent on the degree of dispersion of silver in the layers. [29–1670–6]

EGIN-GOL (also Egiin-Gol), a river in the Mongolian People's Republic, a left tributary of the Selenga River. The Egin-Gol is 475 km long and drains an area of 49,100 sq km. It originates in the lake Khubsugul and flows through a broad valley between mountains and hills; the river has many rapids. The water level rises in the spring, and in the summer there are freshets caused by the rains. The mean flow rate 40 km from the mouth is 100 cu m per sec. The Egin-Gol is frozen over for five or six months a year. The river is not navigable. The landing of Khatgal is situated on the shores of Khubsugul, the source of the Egin-Gol. [29–1675–1]

EGK, WERNER. Born May 17, 1901, in Auchsesheim, near Augsburg. German composer and musical figure (Federal Republic of Germany). Member of the Bavarian Academy of Fine Arts (1951).

Egk received his musical education at the Augsburg Conservatory and pursued further study in Munich with C. Orff. He became known in the 1930's as a conductor and took up residence in Munich in 1954. Egk's work, which developed under the influence of R. Strauss, Hindemith, and Stravinsky, is based on elements drawn from the folklore of ancient Germany, which are transformed through various modern compositional techniques. Egk's finest compositions have generally been written to his own librettos taken from the classics of world literature. Examples are the operas *Peer Gynt* (1938, based on the play by Ibsen), *The Inspector-General* (1957, based on the play by Gogol), and *Betrothal in Santo Domingo* (1963, based on themes from the short story by Kleist). Egk has served as head of the German Composers' Association. [29–1675–4]

EGMONT, COUNT OF (also Lamoral of Egmont). Born Nov. 18, 1522, in La Hamaide; died June 5, 1568, in Brussels. A leader of the oppositional nobility before and during the Netherlands bourgeois revolution of the 16th century.

Egmont opposed only the extreme elements of Spanish policy in the Netherlands and, after the people's Iconoclastic Uprising of 1566, sought a reconciliation with the Spanish government. Nevertheless, he was executed together with Philippe de Montmorency, count of Hoorn. Egmont is portrayed in an idealized manner in Goethe's drama *Egmont* (1788), incidental music to which was composed by L. van Beethoven in 1810. [29–1676–1]

EGOCENTRISM, an attitude toward the world marked by a concentration on oneself; an extreme form of egoism. In philosophy, egocentrism leads to solipsism; in ethics, to individualism. In J. Piaget's genetic psychology, egocentrism characterizes the stage of development of the child between the ages of three and six and dominates his thinking and speech in this stage. The concept of egocentrism is also used in psychopathology and in several schools of depth psychology, including that of A. Adler.

[29–1676–4]

EGOISM, an ethical stance in which private interests are viewed as the basic motive for all action and as the chief criterion of value applied to society and to an individual's immediate milieu.

Egoism arose with the decay of the primitive communal system and the appearance of private property. It reflected the atomization of social associations and the separation from them of self-sufficient individuals, closed groups, and later, classes, for all of which socially useful activity was, and was regarded as, only a means of consolidating and maintaining their social position.

With the development of the commodity, and especially the capitalist, mode of production, private interests, objectively turned into the goal of action, and the principle of egoism became the universal measure of human enterprise. The principle of egoism underlay the philosophical, political-economic, and moral doctrines of such representatives of the Enlightenment as T. Hobbes, B. Mandeville, A. Smith, D. Ricardo, C. Helvétius, P. Holbach, and J. Bentham, the last of whom advocated the ethic of utilitarianism. With later thinkers, such as M. Stirner, adherence to the principle of egoism frequently took the form of extreme individualism and amorality.

Completely unlimited egoism has always been condemned by ordinary moral consciousness. The principle of altruism was advanced as an alternative to it. Only with the elimination of private property under socialism, however, did egoism cease to be the basic means of motivating social activity; it was supplanted by the principle of collectivism. The final elimination of egoism from human relations will take place in the age of mature communism.

O. G. Drobnitskii [29–1676–2]

EGRESSY, GÁBOR. Born Nov. 1, 1808, in Sajólászlófalva; died July 30, 1866, in Pest. Hungarian actor; prominent representative of the romantic revolutionary trend in the Hungarian theater. Friend and comrade of S. Petőfi; participant in the Hungarian Revolution and national liberation struggle of 1848–49.

Egressy began his stage career in 1828. Beginning in 1837, he worked primarily in the first permanent theater in Pest, named the National Theater in 1840. His powerful temperament suited him to heroic and tragic roles, notably the title roles in Shakespeare's *Hamlet, Othello*, and *Richard III*. Egressy gave the first truly profound interpretations of roles of the Hungarian repertoire. In 1834 he appeared in Katona's *Bánk bán*, as Otto; he later played Petur in the same play and in the 1840's undertook the title role.

Egressy was the author of *The Actor's Art* (1866), which reflects his progressive views on the stage arts.

EĞRİDİR, a lake in southwestern Turkey, in the northwest spurs of the Taurus Mountains; situated in an intermontane basin at an elevation of 924 m. Lake Eğridir has a length of approximately 50 km and an area of approximately 320 sq km. The shores of the south side of the lake are steep, but those on the north side, around the isolated reach known as Hoyran, slope gently. The Eğridir is a freshwater lake, although there is no surface runoff. It is thought that water drains from the lake through karst cavities underground. [29–1677–1]

EGRISI (also Mingrelian), a mountain range in the Greater Caucasus, in the Georgian SSR. The Egrisi Range is parallel to the Glavnyi, or Vodorazdel'nyi, Range and extends from the Inguri River to the Tskhenistskali River. It reaches a maximum elevation of 3,173 m at Mount Tsekuri. Forests of broad-leaved trees, such as oak and beech, grow on the slopes of the range. Subalpine and alpine meadows are found above 2,000 m. [29–1677–2]

EGUCHI KIYOSHI. Born July 20, 1887, in Tokyo; died there Jan. 18, 1975. Japanese writer.

Eguchi studied at the division of English literature of the University of Tokyo. He joined the socialist movement in 1920. Eguchi was a prominent figure in Japanese proletarian literature in the 1920's and 1930s. His early short stories, written between 1910 and 1920, reveal elements of aestheticism; however, burning social issues are typical of the short stories "The Lieutenant and the War Invalid" (1919) and "In the Cell of Preliminary Confinement" (1922). The novella *Love and Prison* (1923; Russian translation, 1927) is devoted to the life and struggle of Japanese revolutionaries. The novella *The Bride and the Horse* (1949) portrays the life of Japanese peasants. Eguchi was the author of the memoirs *Half a Century of My Life in Literature* (vols. 1–2, 1953–58).

EGVEKINOT, an urban-type settlement and the administrative center of Iul'tin Raion, Chukchi Autonomous Okrug (formerly Chukchi National Okrug), Magadan Oblast, RSFSR. A port on the Krest Gulf of the Bering Sea, Egvekinot has an ore-dressing combine, a construction combine, and a food-processing combine. [29–1670–5]

EICHENDORFF, JOSEPH VON. Born Mar. 10, 1788, at Lubowitz Castle; died Nov. 26, 1857, in Neisse. Baron; German writer.

Eichendorff studied at the University of Halle in 1805 and 1806 and at the University of Heidelberg in 1807 and 1808. He fought in the war of liberation of 1813 against Napoleon. Eichendorff's poems were first published in 1808. His lyrics, which are devoid of tragedy or dark overtones, contain vivid depictions of nature, in harmonious union with which is the figure of the romantic poet. His songs are an intrinsic part of his prose works, such as his novella *Memoirs of a Good-for-nothing* (1826; Russian translation, 1935) and his short stories and novels. Many of Eichendorff's songs were set to music by F. Schubert, F. Mendelssohn, and R. Schumann. Tendencies toward realism appear in his later works. Eichendorff also was the author of works of literary history.

EICHHORN, EMIL. Born Oct. 9, 1863, near Chemnitz; died July 26, 1925, in Berlin. Figure in the German working-class movement; journalist. Member of the Communist Party of Germany from 1919.

Eichhorn became an active member of the Social Democratic Party in 1893 and served as head of the Social Democratic press bureau from 1908 to 1917. In 1917 he joined the Independent Social Democratic Party of Germany and became the head of its press service. In 1918 he was on the staff of the Russian Telegraph Agency in Berlin. During the November Revolution of 1918, the Berlin Council appointed Eichhorn chief of police in Berlin; he supported the revolutionary workers and soldiers. Eichhorn's dismissal by the Prussian government on Jan. 4, 1919, led to a protest staged by the working people of the city; the protest gained strength and resulted in general turbulence lasting several days.

Eichhorn became a deputy to the Weimar Constituent Assembly in 1919 and was elected to the Reichstag several times. [29–1733–2]

EICHHORN, KARL FRIEDRICH. Born Nov. 20, 1781, in Jena; died July 4, 1854, in Cologne. German jurist and historian of law; one of the main representatives of the historical school of law.

Eichhorn was a professor in Frankfurt an der Oder from 1805 to 1811, in Berlin from 1811 to 1813, in Göttingen from 1816 to 1829, and again in Berlin from 1832 to 1847. His main scholarly work was the *History of the German State and Law* (1808–23).

Eichhorn was one of the founders of the historical school of law, which drew on all the sources available to scholarship at that time. He traced the development of Germanic law, as well as the history of state institutions and of some social institutions, from ancient times to 1815. He believed that the state and law are a product of organic development rather than arbitrary acts of legislators and that the nature of the state and legal systems is determined by the "folk spirit."

Eichhorn's outlook was strictly conservative. He was hostile to French bourgeois institutions, and he defended Germanic law, which was derived from feudalism. Eichhorn considered the communal mark, the aristocracy, and retainership to be original German institutions.

EICHLER, AUGUST WILHELM. Born Apr. 22, 1839, in Neukirchen; died Mar. 2, 1887, in Berlin. German botanist.

Eichler graduated from the University of Marburg in 1860. He taught at the University of Munich beginning in 1865 and became professor at the university of Graz (1871), Kiel (1872), and Berlin (1878). His main works dealt with the systematics and comparative morphology of vascular plants. In *Diagrams of Flowers* (parts 1–2, 1875–78), he surveyed the comparative morphology of flowers of angiosperms. Eichler proposed a phylogenetic system of plants, which was developed by A. Engler.

EICHMANN, ADOLF. Born Mar. 19, 1906 in Solingen in the Rhineland; died June 1, 1962, in Ramleh, Israel. Fascist German war criminal.

Eichmann joined the security service of the SS (Schutzstaffel) in 1934 and subsequently headed the subsection on Jewish affairs. In World War II he helped to draft and implement plans for the physical extermination of the Jewish population in Europe, and he was directly in charge of the shipment of Jews to concen-

tration camps. After the defeat of fascist Germany, Eichmann fled to Argentina. In 1960 he was seized by agents of the Israeli intelligence service. Eichmann was sentenced to death after being tried by a court in Jerusalem and was executed in the prison in the city of Ramleh. [29–1735–3]

EIDEMAN, ROBERT PETROVICH (also R. P. Eidemanis). Born Apr. 27 (May 9), 1895, in the village of Lejasciems, in what is now Gulbene Raion, Latvian SSR; died June 12, 1937. Soviet military commander. Corps commander (1935). Member of the CPSU from 1917.

Eideman graduated from the Valka Realschule in 1914 and entered the Petrograd Institute of Forestry. He was called into the army in 1916. After graduating from the Kiev Military School in the same year, he became an ensign and was assigned to Kansk as commander of a battalion in the 16th Siberian Reserve Rifle Regiment. After the February Revolution of 1917 he was elected chairman of the Kansk soviet of soldiers' deputies. In October 1917, at the First All-Siberian Congress of Soviets, Eideman was elected deputy chairman of the Central Executive Committee of Siberian Soviets (Tsentrosibir').

Eideman joined the staff of the Western Siberia headquarters in May 1918 and led detachments of the Red Guard against the counterrevolutionary Czechoslovak troops and White Guards in the Omsk region. Over a period beginning in July 1918 he commanded the 2nd and 3rd Urals divisions and the Special Division of the Third Army of the Eastern Front. He was commander of the 16th, 41st, and 46th rifle divisions on the Southern Front between March 1919 and April 1920, chief of rear services of the Southwestern Front in April and May 1920, and commander of the Thirteenth Army in June and July. From July to September 1920, as commander of the Right-bank Group of Forces of the Southwestern Front, he defended the Kakhovka base of operations. Eideman was commander of the interior service of the Southern and Southwestern fronts from October 1920 to January 1921. From February to May 1921, he was commander of the Kharkov Military District, where he directed the effort to control banditry. Eideman was assistant commander and then deputy commander of the armed forces of the Ukraine and the Crimea between 1921 and 1924 and commander of the Siberian Military District from 1924 to 1925.

Eideman served as director of the M. V. Frunze Military Academy and as its commissar from 1925 to 1932. He was managing editor of the journal *Voina i revoliutsiia* from 1927 to 1936. A member of the Revolutionary Military Council of the USSR from 1932 to 1934, he became a member of the Military Council of the People's Commissariat of Defense in 1934. In 1932, Eideman was made chairman of the Society for Assistance to Defense, Aviation, and Chemical Construction of the USSR (Osoaviakhim).

Eideman was the author of works on verse and prose. He was a member of the board of directors and chairman of the Latvian section of the Union of Writers of the USSR and a member of several convocations of the All-Russian Central Executive Committee and of the Central Executive Committee of the USSR. Eideman was awarded two Orders of the Red Banner and the Order of the Red Star.

EIDETIC MEMORY, a particular type of pictorial memory, primarily of visual impressions, that permits one to retain and reproduce an extraordinarily vivid image of a previously perceived object—an image that in clarity and detail is almost a copy of the originally perceived image.

Eidetic memory is present in some form and to some degree in all persons, and especially in children and teen-agers, but is seldom encountered in a clear-cut form. One of the first to describe eidetic memory was the Russian researcher Urbanchich (1907). The basic research on eidetic images was done by the German psychologist E. Jaensch and his students in the 1920's.

EIDINOV, GRIGORII BORISOVICH. Born Aug. 28 (Sept. 10), 1908, in Baku; died May 2, 1977, in Minsk. Soviet party and state figure. A leader of the partisan movement in Byelorussia during the Great Patriotic War of 1941–45. Member of the CPSU from 1927.

The son of a worker, Eidinov graduated from the Higher Party School Under the Central Committee of the CPSU in 1958. Beginning in 1928, he engaged in work for the Komsomol and the party in Moscow and Byelorussia. From 1940 to 1944 he was secretary of the Central Committee of the Communist Party of Byelorussia (Bolshevik). In 1942, Eidinov headed the northwest command group of the Central Committee and of the Council of Peoples Commissars (CPC) of the Byelorussian SSR set up to organize partisan detachments and the party underground in occupied Byelorussia. From 1942 to 1944 he was first deputy chief of the Byelorussian headquarters of the partisan movement.

In 1944, Eidinov became deputy chairman of the Byelorussian CPC (renamed the Council of Ministers in 1946) and chairman of the Gosplan (State Planning Committee of the Byelorussian SSR). In 1948 he took up an administrative position on the staff of the Council of Ministers of the RSFSR. He served as a deputy to the second convocation of the Supreme Soviet of the USSR. Eidinov was awarded the Order of Lenin, three other orders, and various medals. [29–1699–1]

EIDLIN, LEV ZALMANOVICH. Born Dec. 23, 1909 (Jan. 5, 1910), in Chernigov. Soviet scholar, translator, and professor (since 1969) of Chinese literature. Member of the CPSU since 1932.

Eidlin graduated from the N. N. Narimanov Moscow Institute of Oriental Studies in 1937; his doctoral dissertation was entitled *T'ao Yüan-ming and His Poetry* (1968; book of the same title, 1967). He is the author of *On Chinese Literature of Our Times* (1955), *Chinese Literature* (1962; with V. F. Sorokin), and articles on the history of Chinese literature and theater and on the theory of translating poetry. He has translated the works of Po Chü-I, T'ao Yüan-ming, and other poets.

EIDOS, a term that was originally used in ancient philosophy and literature to designate the visible, or "that which is seen," but that gradually acquired a deeper meaning—"concrete manifestness," or "physical or plastic givenness in thought."

For Homer the term meant "outward appearance," and primarily "beautiful outward appearance." In ancient natural philosophy (Empedocles and Democritus) eidos was interpreted al-

most exclusively as "image." Parmenides, however, regarded it as the essence, or truth, that is visible in one way or another. Plato's eidos had different meanings, such as "the external," "the internal," or even the characteristically Platonic "substantial idea." Aristotle used eidos to mean "form" as well. In Stoicism and Neoplatonism the term ranges in meaning from "body appearance" to "independent substantial idea."

In the phenomenology of E. Husserl, eidos, or rather its Latin translation *species*, designates the highest intellectual abstraction that is nonetheless a concrete, obvious, and entirely independent given.

EIDSVOLL CONSTITUTION OF 1814, the constitution of Norway; adopted on May 17, 1814, by the Constituent Assembly in the city of Eidsvoll.

The Eidsvoll Constitution was adopted after the Danish king had been forced to renounce the Norwegian crown; in accordance with the Treaties of Kiel (1814), the crown was to pass to Sweden, but Norway was preparing to resist Sweden's plans for annexation. The Eidsvoll Constitution proclaimed Norway an independent state, and it recognized a parliament known as the Storting to be the supreme representative body. The members of the Storting were to be chosen by direct election, but with age, property, and residence qualifications for voting; the body was given broad legislative and financial powers. The king was granted executive power over the country's administration, defense, and foreign policy; he could not dissolve the Storting, however, and although he could supervise legislation, he had only qualified veto power over the parliament's decisions. The constitution introduced the freedoms of speech, press, and enterprise, and it proclaimed the inviolability of the person.

Norway was united with Sweden in 1814, but in accordance with the law that confirmed this action, Sweden pledged to recognize the Eidsvoll Constitution, as amended to allow for the union of the two countries. The constitution is still in force in Norway, although some changes and amendments were made in, for example, 1905, 1935, and 1946 (*see* NORWAY: Constitution and government). [29–1700–1]

EIDUKEVIČIUS, PRANAS (also Frants Vikent'evich Eidukevich). Born Sept. 25 (Oct. 7), 1869, in Kybartai, in what is now Vilkaviškis Raion, Lithuanian SSR; died Mar. 7, 1926, in Moscow. One of the organizers of the Communist Party of Lithuania. Member of the Communist Party from 1918.

The son of a railroad worker, Eidukevičius was himself a metalworker. He joined the revolutionary movement in the late 1880's, working first in Kaunas and then in Riga and Grodno. He took part in the Revolution of 1905–07 in Łódź and in Vilnius. From 1906 to 1918, Eidukevičius was a member of the Central Committee of the Social Democratic Party of Lithuania and a contributor to the Bolshevik newspapers *Sotsial-demokrat* and *Pravda*. He was arrested several times.

Eidukevičius was chairman of the Central Bureau of Workers' Trade Unions in Vilnius from 1915 to 1918. He began working in the party's underground in May 1918. In October, he helped organize the First Congress of the Communist Party of Lithuania and was elected chairman of the Central Committee. Eidukevičius helped establish Soviet power in Lithuania and was chairman of the presidium of the Vilnius city soviet. After the fall of Soviet power in Lithuania in 1919, he held high government and economic posts in the RSFSR. Eidukevičius was a delegate to the Tenth Congress of the RCP(B).

EIFEL, the western part of the Rhenish Slate Mountains, north of the Mosel River, in the Federal Republic of Germany. The Eifel is approximately 90 km long and rises to an elevation of 747 m in the Hohe Acht. It consists primarily of slates overlain in places by basalts and tuffs. There is a plateau characterized by volcanic forms such as maars and the domes of extinct volcanoes. There are numerous lakes. Peat bogs and heaths are encountered, and coniferous and mixed forests are found in the northwest. The Sudeifel and Nordeifel natural parks are in the Eifel. [29–1731–5]

EIFELIAN STAGE, the lower stage of the Middle Devonian system (period). The Eifelian was established in the Eifel Mountains (in what is now the Federal Republic of Germany) in 1848 by the Belgian geologist A. Dumont. The stratotype of the Eifelian is represented chiefly by marls. In the Ardennes of Belgium it corresponds approximately to the shales of the Couvinian stage of J. d'Omalius d'Halloi, whose base is stratigraphically lower than the base of the Eifelian.

In the USSR the Eifelian (Couvinian) is taken to be more inclusive than in the stratotype and includes the analogues of the Zlihovian stage of Czechoslovakia and the upper part of the Emsian stage of the Rhine region. The Eifelian, which is divided into two substages, is widespread and represented by various rocks, such as marine carbonate and terrigenous rocks, evaporites, continental detrital rocks, and effusive rocks. In the USSR, complex ores, bauxites, iron, manganese, titanium, petroleum, rock salt, and other mineral products are associated with Eifelian beds.
[29–1731–6]

EIFFEL, ALEXANDER GUSTAVE. Born Dec. 15, 1832, in Dijon; died Dec. 28, 1923, in Paris. French structural engineer.

Eiffel graduated from the Ecole Centrale des Arts et Manufactures in Paris in 1855. He used metal structural members to build a number of bridges, viaducts, and other structures, including a bridge over the Douro River at Porto, Portugal. Eiffel became world famous for the wrought-iron latticed tower known as the Eiffel Tower, which is approximately 300 m high and was built according to his specifications for the Paris International Exposition of 1889 as a symbol of the technological achievements of the 19th century. During the erection of the tower, a number of advanced assembly methods were used.

Beginning in 1900, Eiffel devoted himself mainly to research in aerodynamics.

EIGEN, MANFRED. Born May 9, 1927, in Bochum. German physical chemist (Federal Republic of Germany).

Eigen graduated from the University of Göttingen in 1951. He joined the staff of the Max Planck Institute of Physical Chemistry in 1953 and became chairman of the institute in 1964.

Eigen's principal works are devoted to the development of methods for investigating the kinetics of chemical reactions. He proposed a class of methods known collectively as the relaxation method for studying extremely fast chemical reactions. The term is used to describe a method in which the chemical equilibrium of a system is disturbed and the rate at which the system returns to equilibrium is observed; the equilibrium is disturbed by sending a single energy pulse or periodic pulses through the system in order to affect such factors as temperature, pressure, and electric field. Using this method, Eigen and his colleagues studied, for example, the kinetics of reactions of hydrogen and hydroxyl ions in aqueous solutions with acid-base indicators. Another important study involved the kinetics of the association of carboxylic acids.

Together with R. Norrish and G. Porter, Eigen won a Nobel Prize in 1967.

EIGHTS COAST, a section of the coast of Ellsworth Land, in Western Antarctica. Eights Coast extends more than 500 km from 85° to 102° W long.; a large part of the coast is occupied by the Abbot Ice Shelf. The mountainous Thurston Island, which reaches a maximum elevation of 1,000 m, is situated in the western part of the region. Eights Coast was named for J. Eights, who in 1829 and 1830 was the first American geologist to visit the antarctic. [29–1731–3]

EIJKMAN, CHRISTIAAN. Born Aug. 11, 1858, in Nijkerk, Gelderland; died Nov. 5, 1930, in Utrecht. Dutch bacteriologist and physician.

Eijkman earned his doctorate in medicine from the University of Amsterdam in 1883 and worked under R. Koch in Berlin. He served as an army physician in Indonesia in 1886, became director of the Batavian Laboratory of Pathology in Jakarta in 1888, and served as professor of hygiene at the University of Utrecht in The Netherlands from 1898 to 1928. Eijkman, whose works were mainly concerned with vitamins, discovered that vitamin deficiency is the cause of several diseases.

Eijkman was awarded a Nobel Prize in 1929, together with F. Hopkins. [29–1707–2]

EIKE VON REPGAU (also Eike von Repkow). Born circa 1180; died after 1233. German jurist; member (*Schöffe*) of a jurymen's court.

Eike von Repgau was the compiler of the *Saxon Mirror*. The *Saxon World Chronicle* (early 1230's), the first historical work written in Low German, has also been attributed to Eike von Repgau. [29–1705–3]

EIKHE, GENRIKH KHRISTOFOROVICH. Born Sept. 29 (Oct. 12), 1893, in Riga; died July 25, 1968, in Jurmala. Soviet military commander and military historian.

The son of a worker, Eikhe graduated from the Riga Commercial School in 1914 and the Petergof School for Ensigns in 1915. He served in World War I as a company commander and as a staff captain. Eikhe was elected a member of his regimental committee after the February Revolution of 1917 and was chairman of the military revolutionary committee of the 245th Infantry Regiment during the October Revolution. In November 1917 he was elected to the soviet of soldiers' deputies of the Tenth Army. Eikhe volunteered for the Red Army in March 1918, after serving as a member of the collegium on the formation of the Red Guard and after helping suppress the revolt of General J. Dowbór-Muśnicki's Polish Corps.

Between August 1918 and November 1919, Eikhe served on the Eastern Front, commanding a regiment, a brigade, and, from April 1919, the 26th Rifle Division. He served as Fifth Army commander from November 1919 to January 1920 and as commander in chief of the People's Revolutionary Army of the Far East Republic from March 1920 to April 1921. From 1921 to 1923, Eikhe was troop commander in the Minsk region and in Fergana Oblast. In 1924 he joined the People's Commissariat of Foreign Trade.

Eikhe was the author of several works on the history of the Civil War in Siberia. He was awarded the Order of Lenin, two Orders of the Red Banner, and various medals.

EIKHE, ROBERT INDRIKOVICH (in Latvian, Roberts Eihe). Born July 31 (Aug. 12), 1890, on the Avotiņu estate in Dobele District, Courland Province; died Feb. 2, 1940. Soviet state and party figure. Member of the Communist Party from 1905.

The son of a farmhand, Eikhe became a metalworker. In 1908 he joined the city committee of the Social Democracy of the Latvian Territory (SDLT) in Mitava (now Jelgava). After leaving Latvia in late 1908, he took part in the work of the London group of the SDLT. In 1911 he returned to Riga, and in 1914 he became a member of the Central Committee of the SDLT. In 1915, Eikhe was exiled to Siberia, but he escaped. He became a member of the presidium of the Riga soviet in 1917. During the German occupation, he engaged in underground work.

In 1919, Eikhe became people's commissar for foodstuffs of Soviet Latvia. After the fall of Soviet power in Latvia, he performed executive work in the People's Commissariat for Foodstuffs of the RSFSR until 1924. From 1925 to 1927 he was chairman of the Siberian Krai Executive Committee and secretary of the Western Siberian Krai Committee of the ACP(B). In October 1937 he became people's commissar of agriculture of the USSR.

Eikhe was a delegate to the Fourteenth through Seventeenth Party Congresses. At the Fourteenth and Fifteenth Congresses he was named a candidate member of the Central Committee of the ACP(B), and at the Sixteenth and Seventeenth Congresses, a member. Eikhe became a candidate member of the Politburo of the Central Committee of the ACP(B) in 1935. In 1921 he served as a delegate to the Third Congress of the Comintern. Eikhe was a member of the Central Executive Committee of the USSR.

Eikhe was awarded the Order of Lenin.

EIKHENBAUM, BORIS MIKHAILOVICH. Born Oct. 4 (16), 1886, in the city of Krasnyi, in what is now Smolensk Oblast; died Nov. 24, 1959, in Leningrad. Soviet literary scholar; doctor of philology; professor at various higher educational institutions in Leningrad.

Eikhenbaum graduated from the faculty of history and philology of the University of St. Petersburg in 1912. In 1918 he joined the Society for the Study of Poetic Language (OPOIAZ). Eikhenbaum dealt with problems of structure, rhythm, and style in such studies as "How Gogol's 'Overcoat' Was Made" (1919) and *The Melody of Russian Lyric Verse* (1922). These works are noticeably influenced by the principles and inconsistencies of the formal method in literary scholarship. In his later works, which dealt primarily with L. N. Tolstoy (*L. Tolstoi*, books 1–3, 1928–60) and M. Iu. Lermontov, Eikhenbaum adopted a more balanced approach. He analyzed writers' works against a broad historical, social, and cultural background, employing large quantities of biographical, documentary, and archival materials. He never returned to the solitary study of structure that characterized his early, formalist writings.

Eikhenbaum's best works are noted for the acuteness with which he poses literary problems, the originality of his insights, and the elegance of his exposition. One of the foremost Soviet textual critics, Eikhenbaum edited works by such writers as I. S. Turgenev, N. S. Leskov, and M. E. Saltykov-Shchedrin.

EIKHENVAL'D, ALEKSANDR ALEKSANDROVICH. Born Dec. 23, 1863 (Jan. 4, 1864), in St. Petersburg; died 1944. Russian physicist.

Eikhenval'd graduated from the St. Petersburg Institute of Railroad Engineers in 1888 and became an engineer. In 1897, after graduating from the Kaiser Wilhelm University (the University of Strasbourg), he joined the staff of the Moscow Engineering School; he was the director of the school from 1905 to 1908. In 1901, Eikhenval'd became a teacher in advanced courses for women. He taught at Moscow University from 1906 to 1911 and from 1917 to 1920. He emigrated in 1920.

Eikhenval'd demonstrated experimentally that a magnetic field arises during the mechanical movement of electrified bodies. In 1904 he proved that convection currents and conduction currents

are equivalent. In the same year, he became the first to show experimentally that a magnetic field is created when the polarization of a dielectric changes, that is, in the presence of displacement currents. In 1908 he performed a theoretical study of the propagation of energy during the total internal reflection of light. In 1934, Eikhenval'd carried out a theoretical investigation of the properties of large-amplitude acoustic waves.

[29–1734–3]

EIKHFEL'D, IOGAN GANSOVICH. Born Jan. 13 (25), 1893, in the city of Paide, in what is now the Estonian SSR. Soviet biologist, plant breeder, and public figure. Academician of the V. I. Lenin All-Union Academy of Agricultural Sciences (1935) and of the Academy of Sciences of the Estonian SSR (1946; president, 1950–68). Corresponding member of the Academy of Sciences of the USSR (1953). Hero of Socialist Labor (1963). Member of the CPSU since 1961.

In 1923, Eikhfel'd graduated from the Petrograd Agricultural Institute, where he was a student of N. I. Vavilov. In that year he also organized the Khibiny Agricultural Experiment Station in Murmansk Oblast; he was director of the station until 1930. From 1930 to 1940, after the station was reorganized, he was head of its arctic division. Eikhfel'd also directed the Arctic Experiment Station of the All-Union Institute of Horticulture. From 1940 to 1951 he was director of the All-Union Institute of Horticulture. Eikhfel'd was chairman of the Presidium of the Supreme Soviet of the Estonian SSR and vice-chairman of the Presidium of the Supreme Soviet of the USSR (1958–61).

Eikhfel'd's work has been devoted mainly to problems of growing crops in the Far North, reclamation and cultivation of bog and mineral soils of the north, and the development of various new farming practices. He has bred early-maturing varieties of basic crops regionalized for the North.

Eikhfel'd was a delegate to the Twenty-second Congress of the CPSU and deputy to the fourth to sixth convocations of the Supreme Soviet of the USSR. He received the State Prize of the USSR in 1942 and has been awarded six Orders of Lenin, the Order of the October Revolution, four other orders, and several medals. [29–1736–1]

EIKHVAL'D, EDUARD IVANOVICH (Karl Eduard von Eichwald). Born July 4 (15), 1795, in Jelgava, in what is now the Latvian SSR; died Nov. 4 (16), 1876, in St. Petersburg. Russian naturalist. Corresponding member of the St. Petersburg Academy of Sciences (1826).

Between 1814 and 1817, Eikhval'd studied medicine and natural sciences at the University of Berlin. After returning to Russia in 1819 he served as a professor at universities in Dorpat (present-day Tartu; from 1821), Kazan (from 1823), and Vilno (present-day Vilnius; from 1829) and at the St. Petersburg Medical-Surgical Academy (1838–51). Between 1839 and 1855 he lectured on paleontology at the St. Petersburg Mining Institute.

Eikhval'd's main works dealt with the taxonomy of plants and animals, paleontology, geology, and mineralogy. After traveling to the Caucasus and the Caspian Sea (1825–26) and to southwestern Russia (1829), he described several new species of plants and of Caspian-Caucasian fauna, mainly mollusks, fish, and reptiles. He also brought back information on the geography of the regions he visited. In *Zoologia specialis* (vols. 1–3, 1829–31), Eikhval'd provided an outline for the classification of animals based on comparative anatomy, physiology, and paleontology and proposed his own taxonomical system of the animal kingdom.

Eikhval'd was the author of textbooks on mineralogy (*Oryctognosy Mainly With Regard to Russia*, 1844) and geology (*Geognosy Mainly With Regard to Russia*, 1846) and of a textbook on paleontology, which was the only textbook of its kind in the Russian language at that time (*The Paleontology of Russia*, parts 1–2, 1854–61). Between 1860 and 1868, Eikhval'd published *Lethaea Rossica, or The Paleontology of Russia*, a four-volume monograph with an atlas.

EIKONAL (also characteristic function, characteristic), in geometrical optics, a function that specifies the optical path length of a ray of light between two arbitrary points, one (point A) in object space and the other (point A') in image space (*see* IMAGE, OPTICAL).

Depending on the choice of parameters, several different types of eikonals are distinguished. The point characteristic, which is also referred to as Hamilton's characteristic or the characteristic function of Hamilton, is the eikonal of an optical system with respect to the coordinates x, y, and z of A and x', y', and z' of A'. The angle characteristic, which was discovered by H. E. Bruns, is the eikonal of an optical system with respect to a ray's direction cosines μ, ν and μ', ν'. An example of a more complex eikonal is the characteristic function that was discovered by K. Schwarzschild.

In the designing of an optical system, the use of an eikonal makes it possible to obtain expressions for the system's transverse aberrations by differentiating the eikonal with respect to certain parameters. Functions called eikonals are widely used in charged-particle optics in the framework of the general analogy that exists between charged-particle and classical optics. Such functions are also used to describe particle and wave scattering processes in cases where analogies with optics arise. Examples of the techniques employed in such cases include the Hamiltonian method and the eikonal, or slowly varying amplitude, approximation in quantum mechanics and quantum field theory.

EILENBURG, a city in the German Democratic Republic, in Leipzig District, on the Mulde River. Railroad junction. Population, 22,200 (1975). Industry includes the production of Celluloid, construction machinery, furniture, and confectionery. [29–1708–3]

EIMER, THEODOR GUSTAV HEINRICH. Born Feb. 22, 1843, in Stäffa, near Zürich, Switzerland; died May 29, 1898, in Tübingen. German zoologist.

Eimer studied medicine and the natural sciences at the universities of Tübingen, Freiburg, Heidelberg, and Berlin. In 1869 he became a doctor of philosophy. He became a professor at the polytechnic institute in Darmstadt in 1874 and at the University of Tübingen in 1875. Eimer's main works deal with the morphology, histology, and physiology of invertebrates and vertebrates and with the study of variations in the coloration of coelenterates, lepidopterans, and saurians. In his theoretical works, Eimer upheld the theory of the inheritance of acquired traits and the predetermined autonomous development of certain traits (*see* ORTHOGENESIS). In regard to the origin of organisms he supported polygenesis. Eimer was a representative of classical transformism.

EINAUDI, LUIGI. Born Mar. 24, 1874, in Carrù, near Cuneo; died Oct. 30, 1961, in Rome. Italian political and state figure; prominent economist.

Einaudi graduated from the University of Turin. He published a number of economics journals and taught at the universities of Milan and Turin. Between 1943 and 1945 he lived as an exile in Switzerland.

From 1945 to 1948, Einaudi was governor of the Bank of Italy.

He became a member of the Consulta Nazionale (National Council) in 1945 and was elected to the Constituent Assembly as a Liberal in 1946. Einaudi served as vice-premier and minister of the budget in 1947 and 1948. He was the president of the republic from 1948 to 1955, when he was appointed a life member of the Senate.

An author of works on economics and finance, Einaudi was a member or honorary member of many academies and scholarly organizations, both in Italy and abroad. [29–1719–6]

EINDHOVEN, a city in the Netherlands, in the province of North Brabant, on the Drommel River. Population, 192,600 (1977); greater metropolitan area, 360,700.

Eindhoven is an important transportation junction and a major center of the electrical-engineering and electronics industry. Plants of the concern N. V. Philips of the Netherlands produce radio and television equipment, sound-recording and sound-reproduction gear, electronic components, and household electrical appliances. Motor vehicles and bicycles are manufactured in Eindhoven, and the city's light industry includes textiles, leather goods, and footwear. Eindhoven also has a food-processing industry. Eindhoven University of Technology (founded 1956) and a museum associated with the N. V. Philips company are located there. [29–1720–2]

EINHARD (also Eginhard). Born circa 770, in Maingau; died Mar. 14, 840, in Seligenstadt. A figure in the Carolingian renaissance; friend and adviser to Charlemagne.

Einhard was educated in the monastery at Fulda. At the court of Charlemagne he won recognition for his knowledge of science and the arts, and he became an active member of the Academy. He supervised the construction of the cathedral at Aachen and the royal palace at Ingelheim. The *Vita Caroli Magni* (Life of Charlemagne) written by Einhard in Latin after Charlemagne's death enjoyed wide popularity in the Middle Ages. The work contains a great deal of factual information, but owing to his adulation of Charlemagne, Einhard distorted his accounts of the emperor's foreign policy and wars. Some of Einhard's religious works and more than 60 of his letters have been preserved.

EINMANN, EDUARD. Born Jan. 10 (23), 1913, in the village of Kullamaa, in what is now Rapla Raion, Estonian SSR. Estonian graphic artist and painter. People's Artist of the Estonian SSR (1963). Corresponding member of the Academy of Arts of the USSR (1958). Member of the CPSU since 1948.

Einmann studied in Tallinn at the State Higher Art School (the J. Koort School of Applied Art) from 1938 to 1941. He taught at the Tartu Art Institute from 1944 to 1951 and was its director from 1948 to 1951. He founded the Artists' Union of the Estonian SSR in 1943 and was chairman of its administrative board from 1950 to 1957.

Einmann, a master of portrait drawings and engravings, objectively and thoroughly depicts the physical appearance and spiritual world of his subjects. His works are remarkable for their use of chiaroscuro to render form. Notable examples include *V. Loik* (carbon, 1955), *Leili From Vigala* (red chalk, 1958), and *S. Korn* (drypoint, 1960).

Einmann has been awarded the Order of Lenin, three other orders, and various medals.

EINSIEDEL, JOHANN AUGUST VON. Born Mar. 4, 1754, in Lumpzig, near Altenburg; died May 8, 1837, at Scharfenstein Castle, near Zschopau. German materialist philosopher.

Einsiedel was Goethe's and Herder's friend. (Herder's extracts from Einsiedel's works were first published in Berlin in 1957 under the title *Ideen*.) According to Einsiedel, the task of philosophy is to "reduce the spiritual world to the physical world"; in his view, thoughts are the "movements of the brain" caused by the external world's effect on the sensory organs.

Rejecting the biblical myth of creation and the doctrine of the immortality of the soul, Einsiedel defended the idea of the natural origin of life and of man. He considered religion to result from ignorance and described Christianity as the religion of slaves. He criticized religious morality, maintaining that "true morality" is nonreligious. He attacked absolutism and the feudal order on the basis of the principles of enlightenment and democracy, and he condemned political and spiritual oppression. He was convinced that a "golden age" was imminent, when wars would cease, when inequality, injustice, and selfishness would disappear, and when work would become a pleasure. Einsiedel's utopian notions about the society of the future bore the marks of petit bourgeois illusions.

EINSTEIN, ALBERT. Born Mar. 14, 1879, in Ulm, Germany; died Apr. 18, 1955, in Princeton, N.J., USA. Physicist; creator of the theory of relativity (*see* RELATIVITY, THEORY OF) and one of the creators of quantum theory and statistical mechanics.

Beginning at the age of 14, Einstein lived with his family in Switzerland. After graduating from the Zürich Polytechnic in 1900, he taught, first in Winterthur and then in Schaffhasen. In 1902 he was appointed examiner of patents in the federal patent office in Bern, where he worked until 1909. During these years, Einstein created the special theory of relativity and conducted studies in statistical mechanics, Brownian motion, theory of radiation, and other fields. His work gained renown, and in 1909, Einstein was appointed a professor at the University of Zürich. In 1911–12 he was a professor at the German University in Prague. In 1912, Einstein returned to Zürich, where he was appointed to a chair at the Zürich Polytechnic. In 1913 he was elected a member of the Prussian and Bavarian academies of sciences. In 1914 he moved to Berlin, where he was director of the physics institute and a professor at the University of Berlin. While in Berlin, Einstein completed the formulation of the general theory of relativity and further developed the quantum theory of radiation. For his works in theoretical physics and for the discovery of the laws of the photoelectric effect he was awarded a Nobel Prize in 1921.

In 1933, Einstein was forced to leave Germany, and subsequently he renounced his German citizenship in protest against fascism and left the academy. He then came to the USA, to Princeton, N.J., where he joined the faculty of the Institute for Advanced Study. Here he sought to work out the unified field theory and worked on problems in cosmology.

Theory of relativity. Einstein's principal scientific achievement was the theory of relativity, which essentially is a general theory of space, time, and gravitation. The concepts of space and time that prevailed before Einstein had been formulated by I. Newton in the late 17th century and were not in apparent contradiction with facts until advances in physics led to the development of electrodynamics and in general to the study of motion at speeds close to the speed of light. The equations of electrodynamics (Maxwell's equations) proved to be incompatible with the equations of Newtonian classical mechanics. The contradictions were further exacerbated after the Michelson experiment, the results of which could not be explained within the framework of classical physics.

The special theory of relativity, whose subject is the description of physical phenomena (including the propagation of light) in inertial frames of reference, was published by Einstein in 1905 in near-final form. One of its basic assumptions—the total equivalence of all inertial frames of reference—renders the concepts of absolute space and time of Newtonian physics meaningless. Only those conclusions that are not dependent on the rate of motion of the inertial frame of reference retain physical meaning.

On the basis of these concepts, Einstein derived new laws of motion that reduce, in the case of small velocities, to Newton's laws, and proposed a theory of optical phenomena in moving bodies. Turning to the ether hypothesis, he arrived at the conclusion that the description of an electromagnetic field requires no medium whatever and that theory turns out to be noncontradictory if, in addition to the principle of relativity, it is postulated that the speed of light is independent of the frame of reference. The detailed analysis of the concept of simultaneity and the processes of measurement of time and length intervals (which had also been conducted to some extent by H. Poincaré) demonstrated the physical need for the postulate formulated.

Also in 1905, Einstein published a paper in which he showed that the mass of a body m is proportional to its energy E, and in the following year he derived the famous equation $E = mc^2$, where c is the speed of light in a vacuum. The work of H. Minkowski on four-dimensional space-time was of major importance in helping complete the formulation of the special theory of relativity. The special theory of relativity has become an essential tool of physical research (for example, in nuclear physics and elementary particle physics), and its conclusions have been experimentally confirmed.

The special theory of relativity did not touch upon the phenomenon of gravitation and did not even raise the question of the nature of gravitation or the question of the equations of the gravitational field and the laws governing its propagation. Einstein noted the fundamental importance of the proportionality between the gravitational and inertial masses (the equivalence principle). Attempting to correlate the principle with the invariance of the four-dimensional interval, Einstein arrived at the idea that the geometry of space-time was dependent on matter, and after extensive research he derived (1915–16) the equations of the gravitational field (Einstein's field equations). This work laid the foundations of the general theory of relativity (*see* GRAVITATION).

Einstein attempted to apply his equation to the study of the global properties of the universe. In a 1917 paper he showed that a relation between the density of matter and the radius of curvature of space-time can be obained from the theory's principle of homogeneity. Confining himself to a static model of the universe, however, he was forced to include in the equation a negative pressure (the cosmological constant) to balance the attractive forces. The correct approach to the problem was found by A. A. Fridman (Friedman), who conceived the idea of an expanding universe. These studies gave rise to relativistic cosmology.

In 1916, Einstein predicted the existence of gravitational waves, solving the problem of the propagation of a gravitational perturbation. He thus completed the construction of the foundations of the general theory of relativity.

The general theory of relativity explained (1915) the anomalous behavior of the orbit of the planet Mercury, which could not be explained within the framework of Newtonian mechanics. It predicted the deflection of a light ray in the sun's gravitational field (detected 1919–22) and a shift in the spectral lines of atoms located in a gravitational field (detected 1925). The experimental proof of the existence of these phenomena were brilliant confirmations of the general theory of relativity.

The development of the general theory of relativity in the works of Einstein and his colleagues was connected with the attempt to construct a unified field theory, in which the electromagnetic field is organically linked to the space-time metric, like the gravitational field. These attempts were unsuccessful, but interest in the problem has grown because of the construction of a relativistic quantum field theory (*see* QUANTUM FIELD THEORY).

Quantum theory. Einstein was instrumental in working out the foundations of quantum theory. He introduced the concept of the discrete structure of a radiation field and on the basis of this derived the laws of the photoelectric effect and explained luminescent and photochemical regularities. Einstein's ideas regarding the quantum structure of light (published 1905) were in apparent contradiction with the wave nature of light, a contradiction that was resolved only after the creation of quantum mechanics (*see* QUANTUM MECHANICS).

Successfully developing quantum theory, Einstein arrived in 1916 at the division of radiation processes into spontaneous and induced processes and introduced the Einstein coefficients A and B to define the probabilities of the processes. A consequence of Einstein's reasoning was the statistical derivation of Planck's radiation law from the condition of equilibrium between radiators and radiation (*see* PLANCK'S RADIATION LAW). This work by Einstein forms the basis of modern quantum electronics (*see* QUANTUM ELECTRONICS).

Applying the same statistical approach to the vibrations of a crystal lattice rather than the emission of light, Einstein created the theory of the specific heat of solids (1907, 1911). In 1909 he derived the formula for the energy fluctuation in a radiation field, which confirmed his quantum theory of radiation and played an important part in the rise of fluctuation theory.

Statistical mechanics. Einstein's first study in statistical mechanics (statistical physics) appeared in 1902, in which Einstein, unaware of J. W. Gibbs' research, developed his own version of statistical mechanics, defining the probability of a state as the average over time. This view of the principal assumptions of statistical mechanics led Einstein to develop the theory of Brownian motion (published 1905), which became the basis for the theory of fluctuations.

In 1924, after becoming acquainted with S. Bose's paper on the statistics of light quanta and perceiving its importance, Einstein published Bose's paper along with his comments, in which he extended Bose's theory to an ideal gas. Shortly after, Einstein's work on the quantum theory of an ideal gas appeared. Bose-Einstein statistics arose in this manner (*see* BOSE-EINSTEIN STATISTICS).

Other research. Developing the theory of molecular mobility (1905) and investigating the reality of Ampère currents, which give rise to magnetic moments, Einstein predicted, and with the Dutch physicist W. de Haas, experimentally detected the effects of a change in the mechanical moment of a body upon magnetization (the Einstein–de Haas effect).

Importance of research. Einstein's scientific works were of major importance in the development of modern physics. The special theory of relativity and the quantum theory of radiation formed the foundation of quantum electrodynamics, quantum field theory, atomic and nuclear physics, elementary particle physics, quantum electronics, relativistic cosmology, and other branches of physics and astrophysics.

Einstein's ideas proved to have great methodological consequence. They changed the mechanistic concepts of space and time that had prevailed in physics since Newton's time and led to a new, materialist picture of the universe based on the profound, organic link between these concepts and matter and the motion of matter. Gravitation proved to be one manifestation of this link. Einstein's ideas became the principal component of the modern theory of a dynamic, continuously expanding universe, which has made it possible to explain the extraordinarily broad range of phenomena observed.

Einstein's discoveries were recognized by scientists throughout the world and earned him international prestige. Einstein was greatly disturbed by the sociopolitical events of the 1920's to 1940's and denounced fascism, war, and the use of nuclear weapons. He took part in the antiwar campaign in the early 1930's. In 1940, Einstein signed a letter to the president of the United States calling attention to the danger of the appearance of nuclear weapons in fascist Germany, which was directly responsible for the emergence of nuclear research in the United States.

Einstein was a member of many scientific societies and academies throughout the world, including the Academy of Sciences of the USSR, of which he became an honorary member in 1926.

EINSTEIN, ALFRED. Born Dec. 30, 1880, in Munich; died Feb. 13, 1952, in El Cerrito, Calif. German musicologist.

A music critic in Munich and Berlin, Einstein published the journal *Zeitschrift für Musikwissenschaft* from 1918 to 1933. After the fascists came to power, he lived in Great Britain and Italy, eventually taking up residence in the USA in 1939. An important part of Einstein's work was his bibliographies and dictionaries. He edited and wrote several articles for the ninth, tenth, and 11th editions of H. Riemann's *Dictionary of Music* (1919, 1922, and 1929) and translated and revised A. Eaglefield-Hull's *Dictionary of Modern Music and Musicians*, which he published under the title *New Dictionary of Music* (1926).

Particularly valuable are Einstein's works *The Italian Madrigal* (vols. 1–3, 1939), *Greatness in Music* (1941), and *Music in the Romantic Era* (1947) and his monographs on various composers, including H. Schütz (1928), C. W. Gluck, (1936), W. A. Mozart (1945), and F. Schubert (1951). [29–1725–1]

EINSTEIN, a unit of energy of electromagnetic radiation in the optical range. The einstein, which is used in photochemistry, is equal to $N_A h\nu$, where N_A is Avogadro's number and $h\nu$ is the energy of the photon. It was named in honor of Albert Einstein and is abbreviated E. When a radiant energy of 1 E is absorbed, the photochemical conversion of 1 mole of the substance should occur, according to Einstein's law of photochemical equivalence. It follows from the definition of the einstein that the dimension of the unit is determined by the radiation frequency (ν) (h is Planck's constant). [29–1725–2]

EINSTEIN COEFFICIENTS, coefficients that characterize the probabilities of radiative quantum transitions. The Einstein coefficients were introduced by Albert Einstein in 1916 in the course of his formulation of the theory of the emission and absorption of radiation by atoms and molecules on the basis of the concept of photons. Einstein was the first to advance the idea that stimulated emission existed. The probabilities of spontaneous emission, absorption, and stimulated emission are characterized by the coefficients A_{ki}, B_{ik}, and B_{ki}, respectively, in which the subscripts indicate the direction of the transition between the upper energy level E_k and the lower level E_i. The relations between the Einstein coefficients were originally obtained by Einstein in the course of the derivation of Planck's radiation law from the thermodynamic equilibrium between matter and radiation.

EINSTEIN–DE HAAS EFFECT, an effect whereby a body (a ferromagnetic material), when magnetized along some axis, acquires an angular impulse relative to the axis, which is proportional to the acquired magnetization. The effect was experimentally discovered and theoretically explained in 1915 by Albert Einstein and the Dutch physicist W. de Haas.

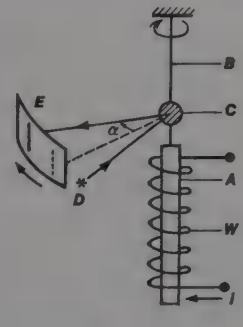

Figure 1. Diagram of apparatus for measuring the Einstein-de Haas effect: (A) sample, (B) elastic thread of suspension device, (C) mirror, (α) angle of rotation of sample, registered from the change in position of the reflected light ray, (D) light source, (E) scale, (W) magnetizing solenoid carrying the current i

A schematic diagram of one of the experimental apparatus for observing the Einstein–de Haas effect is shown in Figure 1. In the apparatus, magnetization of a cylindrical specimen suspended on an elastic thread causes the specimen to rotate by some small angle. The rotation is measured from the angular deflection of a mirror rigidly fixed to the specimen. The effect is explained theoretically by the fact that the magnetic moments of the atoms of the specimen, being oriented in the direction of the external magnetic field, cause a change in the atomic mechanical moments—the magnetic moment **M** of an atom is proportional to the resultant angular momentum **J**, that is, $\mathbf{M} = \gamma\mathbf{J}$, where γ is the gyromagnetic ratio (*see* GYROMAGNETIC RATIO). On the basis of the law of the conservation of angular momentum, the total angular momentum of a body must remain unchanged, and upon magnetization the body therefore acquires an angular impulse (very small in magnitude) that is inverse with respect to the axis of magnetization.

The study of the Einstein–de Haas effect, like that of other gyromagnetic effects, makes it possible to obtain data on the nature of the carriers of magnetism in matter and on the structure of the atoms of a substance (*see* GYROMAGNETIC EFFECTS). In modern physics other effects are used for the same purpose (*see* MAGNETIC RESONANCE).

EINSTEINIUM, Es, a synthetic radioactive chemical element, a member of the actinide series; atomic number, 99. Einsteinium has no stable isotopes; it has known isotopes with mass numbers 243 through 256.

The seventh transuranium element to be discovered, einsteinium was identified by A. Ghiorso and others in December 1952 in the debris from a thermonuclear explosion in the course of work involving members of the University of California Radiation Laboratory, the Argonne National Laboratory, and the Los Alamos Scientific Laboratory (USA). The isotope produced was ^{253}Es, with a half-life of 20.5 days, originating from the beta decay of ^{253}U and daughters; the ^{253}U was formed by the essentially successive capture of 15 neutrons by ^{238}U.

Einsteinium can be investigated with macroscopic quantities using the isotopes ^{253}Es (half-life 20.5 days), ^{254}Es (half-life 276 days), and ^{255}Es (half-life 38.3 days), whose production by the irradiation of lighter elements is severely limited because of the required long sequence of neutron capture reactions over long periods of time in high-neutron-flux reactors. Most of the investigations have used the short-lived ^{253}Es because of its greater availability, but the use of ^{254}Es will increase as it becomes more available. In any case, the investigation of einsteinium is very difficult because of the high specific radioactivity and small available quantities of the isotopes.

Einsteinium metal, which is quite volatile, can be prepared by the reduction of EsF_3 with lithium and has a face-centered cubic crystal structure. The melting point is 860±30°C.

Einsteinium exists in normal aqueous solution in most stable form as Es^{+3} (green), although Es^{+2} can be produced under strong reducing conditions. The Es^{+3}/Es^{+2} reduction potential is estimated to be -1.24 ± 0.2 volt on the scale in which the hydrogen ion–hydrogen potential is 0.0 volt.

Numerous solid compounds, such as Es_2O_3, $EsCl_3$, EsOCl, $EsBr_2$, $EsBr_3$, EsI_2, and EsI_3, have been synthesized and studied.

The electron structure of the gaseous element is $5f^{11}7s^2$ (beyond the radon structure).

EINSTEIN LAW OF PHOTOCHEMICAL EQUIVALENCE, a fundamental law of photochemistry that establishes that every photon absorbed causes one elementary reaction. The reaction may consist in the chemical transformation of molecules of the substance or in their physical excitation and the emission of the energy absorbed (or in the transformation of the energy into thermal energy). The number N of reacted molecules is related to the energy E absorbed by the system by the equation

$$E = Nh\nu = Nh\frac{c}{\lambda}$$

where ν is the frequency of radiation, c is the velocity of light, λ is the wavelength of the light, and h is Planck's constant. The quantity γ (the quantum yield of the photochemical reaction), which is equal to the ratio of the number of reacted molecules of a given substance to the number of light quanta absorbed, is usually the criterion for applicability of the Einstein law of photochemical equivalence. According to the law, γ must be equal to unity.

The deviations from the Einstein law of photochemical equivalence that are frequently observed in nature are usually explained by secondary processes (for more details *see* PHOTOCHEMISTRY). The law was discovered in 1912 by Albert Einstein. [29–1725–3]

EINTHOVEN, WILLEM. Born May 21, 1860, in Samarang, Java; died Sept. 29, 1927, in Leiden, The Netherlands. Dutch physiologist.

Einthoven, upon graduating from the University of Utrecht in 1885, became a professor of physiology at the University of Leiden. His works dealt mainly with electrophysiology. By analyzing electrocardiograms mathematically, Einthoven interpreted the electrical reactions of the heart with unprecedented accuracy. He made a fundamental contribution to clinical electrocardiography in 1903 by devising a string galvanometer.

Einthoven conceived the idea of recording heart currents from three leads, and suggested the use of a triangle to illustrate change in the height of electrocardiographic waves and their interaction in relation to the recording method; he provided a physiological explanation for every wave and interval on the EKG. Einthoven also invented vectorcardiography in 1913. He was one of the first to do research in neuroelectrophysiology. He detected impulses in the depressor nerve and recorded impulses in the pathways of the sympathetic nerves.

Einthoven was awarded a Nobel Prize in 1924.

L. V. SOKOLOVA [29–1721–2]

EIREN, a group leader in the *agele*, a restricted state institution for the upbringing of the young male members of the Spartiates, the Spartan slaveholding aristocracy. *Eirenes* were chosen from among the group members to assist the adult instructors. [29–1729–1]

EIRENE (also Irene), in Greek mythology, the goddess of peace and either the nurse or mother of Plutus, the god of wealth.

Aristophanes' comedy *Eirene* (421 B.C.) depicts the goddess' liberation from the cavern in which the fierce god of war had immured her. A statue by Cephisodotus (first half of the fourth century B.C.) of the beautiful goddess carrying the infant Plutus was erected in Athens circa 374 B.C. The statue survives through various Roman copies, such as the one in the Glyptothek in Munich.

Eirene was venerated in Rome under the name of Pax. In 1957 an international organization of classical scholars from socialist countries was founded under the name "Eirene"; its journal also bears the goddess' name. [29–1728–5]

EISELE, DONN FULTON. Born June 23, 1930, in Columbus, Ohio. US pilot and astronaut; major in the air force.

Eisele graduated in 1952 from the US Naval Academy, where he received the degree of bachelor of science. He also graduated from the Aerospace Research Pilot School at Edwards Air Force Base in California. He was awarded a master's degree in astronautics from the Air Force Institute of Technology at Wright-Patterson Air Force Base in Ohio. He served as an experimental flight test officer at Kirtland Air Force Base in New Mexico. In 1963 he became an astronaut with the National Aeronautics and Space Administration.

From Oct. 11 to Oct. 22, 1968, Eisele, together with W. Cunningham and W. Schirra, undertook a flight in the spacecraft Apollo 7, which orbited the earth 163 times. During the mission, which lasted 10 days 20 hr 9 min, Eisele conducted the first flight test of the command module of the Apollo spacecraft. [29–1701–1]

EISENACH, a city in the German Democratic Republic, in Erfurt District, on the Hörsel River. Population, 50,000 (1975). Eisenach is a railroad junction. Machine building, including the manufacture of Wartburg automobiles, plays an important role in the local economy. The city also has textile, furniture, and chemical industries. Cultural institutions include a museum devoted to J. S. Bach, who was born in the city. Luther and Goethe also lived in Eisenach. [29–1701–3]

EISENACHER, a member of the Social Democratic Workers' Party of Germany, which was founded under the leadership of A. Bebel and W. Liebknecht at an all-German workers' congress in the city of Eisenach in August 1869. Although based on the revolutionary principles of the First International, the party's program contained certain imprecisely formulated propositions. According to the party's charter, democratic centralism was the basic organizing principle of the party.

The Eisenachers defended the line of the First International in the international working-class movement, and they supported the movement's Marxist wing. During the Franco-Prussian War of 1870–71, they adopted an internationalist position and declared their solidarity with the Paris Commune. The Eisenachers were staunch advocates of the unification of Germany by revolutionary means, and they carried on a struggle against the militarist police regime.

At a congress in Gotha in 1875, the Eisenachers and the Lassalleans united to form a single party of the working class (*see* SOCIAL DEMOCRATIC PARTY OF GERMANY). [29–1701–4]

EISENERZ, a city in Austria, in the *Bundesland* (state) of Styria, at the foot of the Eisenerzer Alpen. Population, 11,600 (1971). There is a large deposit of iron ore in the Erzberg, near Eisenerz. [29–1705–1]

EISENHOWER, DWIGHT DAVID. Born Oct. 14, 1890, in Denison, Texas; died Mar. 28, 1969, in Washington, D.C. US statesman and military leader; general of the army (1944).

Eisenhower graduated from the US Military Academy at West Point in 1915 and subsequently served in the American Army in the USA and abroad, in the War Department, and on the Army Staff. With the coming of World War II, Eisenhower was appointed in June 1942 as commander of US forces in Europe, and in November 1942 as commander of Allied forces in North Africa and the Mediterranean. In 1943 he was made supreme commander of Allied Expeditionary Forces in Europe and directed the landing of the British and American forces on the coast of northwestern France. This landing established the second front in Europe. Eisenhower was awarded orders of many countries, among them the Soviet Order of Victory (1945). After the rout of fascist Germany, Eisenhower was appointed commander of US occupation forces in Germany. He was US Army chief of staff from November 1945 to February 1948, and he was supreme commander of the North Atlantic Treaty Organization's armed forces in Europe from 1950 to 1952. During the years 1948–52 he was president of Columbia University in New York.

Eisenhower, a Republican, was president of the United States from 1953 to 1961. In domestic politics, the Eisenhower administration drastically reduced expenditures for social services, supported the anticommunist propaganda unleashed by rightist groups, and openly violated many civil rights guaranteed in bourgeois-democratic societies. In foreign policy, the Eisenhower administration continued the arms race and the cold war and sought to strengthen the strategic position of the USA in various regions of the world. Its military strategy was based on increasing the capabilities of nuclear arms, accelerating the development of strate-

gic aviation, and building a fleet of missile-carrying nuclear submarines. Under Eisenhower, relations with the USSR and other socialist countries were governed by the principle of "brinkmanship," and steps were taken to subvert the socialist order in Central and East European countries (the so-called "liberation" doctrine). The Eisenhower administration initiated a program to create new, aggressive military alliances and to acquire more military bases. An armed intervention against the government of Guatemala was organized in 1954. The Eisenhower doctrine was proclaimed in 1957. It was aimed at strengthening the position of the USA in the Middle East and counteracting the nationalist liberation movement within the area.

The Eisenhower administration, however, recognized the increasing might of the global socialist system and therefore took some realistic steps in the area of international relations. In 1953 an armistice was signed in Korea, and in 1955, Eisenhower took part in the Geneva conference attended by the heads of government of the USA, the USSR, Great Britain, and France. In 1959 the chairman of the Council of Ministers of the USSR accepted an invitation from Eisenhower and paid a state visit to the USA.

[29–1702–1]

EISENHOWER DOCTRINE, a foreign policy position of the US government regarding the Middle East, adopted after the failure of the Anglo-French-Israeli aggression against Egypt in 1956 and the significant weakening of the position of the colonialist powers in the Middle East. It was developed with the assistance of the US secretary of state, J. F. Dulles. The doctrine was first laid out in an address to Congress by the president of the USA, D. D. Eisenhower, on Jan. 15, 1957, and was adopted by means of a congressional resolution in March 1957.

The doctrine was intended to strengthen the position of the USA in the Middle East and to systematically oppose the forces of the national liberation movement. The US president was given the "right" to offer military and economic "aid" to countries in the Middle East and, at his own discretion, to use American armed forces in the area. The doctrine signified the aspiration of the USA to arbitrarily and unilaterally decide questions of war and peace in the Middle East, to interfere in the internal affairs of countries of the area, and to establish control over the foreign policy of these countries. Such objectives were in fundamental contradiction to the interests of peace and security and to the principles of state sovereignty and the independence of peoples. The doctrine grossly violated international law and a number of provisions of the UN Charter. It also violated US constitutional practice, since it bypassed Congress and gave the president virtually uncontrolled military authority.

The USA implemented the doctrine repeatedly (the plots against Syria, 1957; aggression against Lebanon, 1958). The national liberation movements of the peoples of the Arab East—as well as the consistent foreign policy of the USSR and the other countries of the socialist cooperation—directed at ensuring peace and supporting the just demands of the Arab peoples, frustrated the plan of the USA to fully implement the doctrine. However, the basic principles and aims of the Eisenhower doctrine have in open or covert form been a part of US policy regarding the Middle East in later times as well (support of Israel's aggressive actions and of reactionary forces in Arab states). [29–1703–1]

EISENHÜTTENSTADT, a city in the German Democratic Republic, in Frankfurt/Oder District. Port on the Oder-Spree Canal. Population, 47,400 (1975). Eisenhüttenstadt was founded in 1950 in connection with the building of the Ost ferrous metal combine. River vessels are built in the city. In 1961 the city of Fürstenberg merged with Eisenhüttenstadt.

The city is divided into neighborhood districts, each with approximately 6,000 residents. All neighborhoods have squares, parks, and shops. Typical examples of the city's architecture, with three- to five-story buildings predominating, include apartment houses on Heinrich-Heine-Allee and Maxim-Gorky-Strasse (1956, architect W. Stamm), Republikstrasse (1957, architects O. Schmidt and W. Knof), and the House of the Organizations (1955, architect H. Wunderlich).

[29–1703–2]

EISENSTEIN, SERGEI MIKHAILOVICH. Born Jan. 10 (22), 1898, in Riga; died Feb. 11, 1948, in Moscow. Soviet motion-picture director, theoretician of art, and teacher. Honored Artist of the RSFSR (1935). Doctor of arts (1939).

Eisenstein, the son of an architect, studied at the Petrograd Institute of Civil Engineering. In 1918 he went to work on Red Army agitational trains. In 1920 he was in charge of stage design for the First Proletkul't Workers' Theater in Moscow. He studied under V. E. Meyerhold at the State Higher Directing Studios in 1921–22, and together with S. I. Iutkevich he staged a series of performances at the Mastfor Theater (Foregger's Workshop). His first independent production was *The Wise Man*, based on A. N. Ostrovskii's comedy *Even a Wise Man Stumbles* (1923). In 1923, Eisenstein published the article "The Montage of Attractions," in which he expressed his fundamental theories of effecting social change through art.

Eisenstein's *Strike* (released 1925) was the first film to depict the revolutionary masses as the moving force of history. The ideological and aesthetic principles of *Strike* were developed in *Battleship Potemkin* (1925), one of the greatest achievements of Soviet and world film-making. With classical perfection the film embodied the theme of revolution as a struggle for class equality, freedom, and human dignity. At the 1958 World's Fair in Brussels it was ranked first among the 12 best films in history. In *October* (1927), Eisenstein, director G. V. Aleksandrov, and cameraman E. K. Tisse re-created the events of 1917 and made the first attempt to depict V. I. Lenin in a feature film. Advances in montage enabled Eisenstein to promote the idea of the "intellectual cinematographer" as a synthesizer of art and science. In 1929 he completed *Old and New*, the first Soviet film about cooperation and collectivization in the countryside.

Between 1929 and 1932, Eisenstein, Aleksandrov, and Tisse worked in France, the United States, and Mexico. The conditions of capitalist film-making prevented Eisenstein from realizing his artistic dreams. *Que viva Mexico!* remained unfinished, although it did mark the beginning of Mexican film-making.

After returning to his homeland, Eisenstein continued to work as a director, theoretician, and teacher. From 1935 to 1937 he worked on *Bezhin Meadow*, based on the murder of the pioneer Pavlik Morozov, but the film was not completed. *Alexander Nevsky* (1938), a patriotic film about the defeat of the German knights in the 13th century, became a triumph of Soviet film-making. Eisenstein's last motion picture, the tragedy *Ivan the Terrible* (part I, 1945; part II released 1958), dealt with the theme of power. With its profound historical subject matter and intensive use of the expressive devices of the cinema, it became Eisenstein's second masterpiece.

Eisenstein's enormous theoretical heritage covers the fundamental problems of artistic creation, from general aesthetic concepts to concrete problems of film-making. He also wrote sociopolitical articles, essays, and memoirs. His drawings, which have been shown at posthumous exhibitions, reveal his unusual talent in the graphic arts. Eisenstein taught at the State Technicum of Cinematography from 1928, becoming a professor in 1937 (in 1938 it was renamed the All-Union State Institute of Cinematography).

Eisenstein was awarded the State Prize of the USSR (1941, 1946), the Order of Lenin, the Order of the Badge of Honor, and several medals.

EIŠIŠKĖS, a city in Šalčininkai Raion, Lithuanian SSR. The city is located in the southeastern part of the republic, on the Vilnius-Grodno highway. It is 35 km east of the Varėna railroad station and 70 km southwest of Vilnius. Enterprises include a butter factory. [29–1736–2]

EISLEBEN, a city in the German Democratic Republic, in Halle District. Population, 295,000 (1975). Crude copper is produced at the site of the Mansfeld copper-ore deposit. [29–1730–1]

EISLER, HANNS. Born July 6, 1898, in Leipzig; died Sept. 6, 1962, in Berlin. German composer and public figure (German Democratic Republic [GDR]). Member of the Academy of Arts of the GDR.

Eisler studied composition in Vienna with A. Schönberg from 1919 to 1923 and took up residence in Berlin in 1924. Although his early works show the influence of his teacher, Eisler's progressive views, his study of Marxism, and his increasing contacts with the revolutionary movement made his art more democratic. Eisler worked closely with E. Weinert, B. Brecht, and the singer E. Busch, who performed many of his songs for the masses, and he taught and addressed workers' choral groups.

Eisler composed many workers' songs, marches, and ballads on current political topics, such as "Song of Solidarity," "Song of the Unemployed," "Song of the United Front," "Red Wedding," and "The Comintern." He was a founder of a new style of revolutionary song for the masses. In addition, he composed works in the larger forms, including *Requiem for Lenin* (1937) and music for theatrical productions, notably the music to Brecht's *The Measures Taken* (1930).

In 1938, after the fascists had come to power, Eisler emigrated to the USA, where he worked in Hollywood. Accused of un-American activities, he left the USA in 1948 as a "voluntary deportee." He settled in Berlin in 1948 and played an active role in developing the musical culture of the GDR. In 1950 he began teaching composition at the Academy of Arts of the GDR and music theory at the Hochschule für Musik, which is now named in his honor. He helped found the Union of Composers and Musicologists of the GDR.

Eisler's most important works include the cantatas *German Symphony* (1937), *Serenade of the Age* (1950), and *The Carpet-weavers of Kuyan-Bulak* (1957) and the symphonic triptych *Song of Peace* (1951). In his finest works Eisler combines the characteristic features of mass and revolutionary songs with varied means of musical expression. He used polyphony, atonal music, jazz elements, and folk song effects. Rhythm is an important organizing principle in Eisler's vocal music, in which extensive use is made of recitative. His symphonic music is notable for its complex and subtle orchestration.

Eisler composed the national anthem of the GDR (words by Brecht), and he was awarded the National Prize of the GDR in 1949 and 1958.

M. M. IAKOVLEV [29–1730–2]

EISNER, JÁN. Born Apr. 26, 1885, in Bradlo; died May 2, 1967, in Prague. Czechoslovak historian and archaeologist. Academician of the Czechoslovak Academy of Sciences (1952).

Eisner was a professor at Charles University in Prague from 1939 to 1957. His research centered on the prehistoric and ancient periods in Slovakia. He also made important contributions to Slavic archaeology and, in particular, Slavic ethnogeny. Eisner edited the collections entitled *The Origin and Emergence of the Slavs*.

EISNER, KURT. Born May 14, 1867, in Berlin; died Feb. 21, 1919, in Munich. Figure in the German workers' movement; journalist.

Eisner joined the Social Democratic Party of Germany in 1898. From 1898 to 1905 he was editor in chief of the newspaper *Vorwärts*, a party organ, and was closely associated with revisionists. During World War I he assumed an anti-imperialist stance. Eisner became a member of the Independent Social Democratic Party of Germany in 1917. After leading a strike at military plants in Munich in January 1918, he was imprisoned. During the November Revolution of 1918, Eisner was the chairman of the Munich council of workers, soldiers, and peasants; he subsequently became prime minister of the republican government of Bavaria. [29–1730–3]

EISRIESENWELT, a karst grotto in Austria, in the Tennengebirge, 35 km southeast of Salzburg. Eisriesenwelt measures 42 km in length and 407 m in depth. The entrance to the grotto lies at an elevation of 1,641 m, 1,120 m above the bottom of the valley of the Salzach River. For a length of 2 km from the entrance there is an abundant accumulation of ice, which gave the name to the grotto, "giant ice world" in German. [29–1731–2]

EIZEN, ARTUR ARTUROVICH. Born June 8, 1927, in Moscow. Soviet Russian bass. People's Artist of the USSR (1976). Member of the CPSU since 1964.

In 1948, Eizen graduated from the Shchukin Moscow Theatrical School, and in 1956 he graduated from the Moscow Conservatory, where he studied voice under V. M. Politkovskii. He was a soloist with the A. V. Aleksandrov Song and Dance Ensemble of the Soviet Army from 1949 to 1957 and has been a soloist with the Bolshoi Theater since 1957.

Eizen has a high bass of a beautiful mellow timbre. He is also an accomplished actor. He has sung more than 30 roles, including Boris and Varlaam in *Boris Godunov* and Ivan Khovanskii in *Khovanshchina*, both by Mussorgsky, Galitskii in Borodin's *Prince Igor*, Mephistopheles in Gounod's *Faust*, Pestel' in Shaporin's *The Decembrists*, the General in Prokofiev's *The Gambler*, and Vaskov in Molchanov's *Dawns Are Quiet Here*. He performed the role of V. I. Lenin in Muradeli's *October* (1964). Eizen also gives concerts and has toured many countries of the world. [29–1701–2]

EJECTIVE, a consonant articulated with a closure and upward movement of the glottis, as a result of which air is ejected in a sharp burst, giving the effect of a glottal stop. Ejectives are usually stops. They are found in the languages of Asia, America, and Africa and in the Dagestan and Kartevelian languages (*p'*, *t'*, *k'*, *c'*). Fricative ejectives are less common, for example, Hausa *'ya'ya* ("children"). [29–1700–3]

EJECTOR, a device in which kinetic energy is transferred from a medium that is moving at high velocity to another medium. The energy is transferred as the media are mixed (*see* JET APPARATUS). Ejectors are used in jet and vacuum pumps. They are widely used as mixers in the chemical and petroleum-refining industries.

ÉK, SÁNDOR (pseudonym, Alex Keil). Born Aug. 27, 1902, in the village of Szentmihályfalva. Hungarian painter and graphic artist.

Ék studied at the Free Art School in Budapest at the time of the Hungarian Soviet Republic (1919). After the fall of Soviet power in Hungary he emigrated to Germany and, in 1933, to the USSR. He produced revolutionary posters and caricatures of striking design, notably the poster *Ten Years Without Lenin* (1934). After returning to Hungary in 1945 he worked as a graphic artist, producing the series of lithographs *Memento* (1958), and as a painter.

Ék, an unyielding supporter of realist art, was awarded the Kossuth Prize in 1951.

EKA-ELEMENTS, a term introduced by D. I. Mendeleev in 1871 for chemical elements that were predicted by him but still unknown in his time; the elements were arranged in the periodic table under the corresponding known elements. All the eka-elements were later discovered: eka-aluminum (1875) was called gallium; eka-boron (1879), scandium; and eka-silicon (1886), germanium. Mendeleev also predicted the existence of analogues of manganese (future Tc and Re), and tellurium (Po), iodine (At), cesium (Fr), barium (Ra), and tantalum (Pa).

The term "eka-element" is sometimes used to designate transuranium elements that have not yet been discovered and synthesized; for example, element no. 118 is called eka-radon. (*See also* PERIODIC SYSTEM OF ELEMENTS.)

EKHOF, KONRAD. Born Aug. 12, 1720, in Hamburg; died June 16, 1778, in Gotha. German actor and theatrical figure.

Ekhof began his stage career in 1740 in Hamburg, appearing with J. Schönemann's company. He appeared with the companies of H. Koch and K. Ackermann, and from 1767 to 1768 performed at the National Theater in Hamburg. He was the favorite actor of G. E. Lessing, with whom he held many common views, and was the first interpreter of bourgeois Enlightenment drama on the German stage.

Ekhof helped develop a theory of acting and was a superb teacher; his student F. L. Schröder was an outstanding reformer of the German stage. Basing his generalized theories on stage experience, Ekhof established the Academy of the Schönemann Society in Schwerin in 1753. Ekhof also was a critic, translator, and historian of the German theater.

Ekhof was famous for his performances as Barnwell in Lillo's *The London Merchant* and Odoardo, Mellefont, and Tellheim in Lessing's *Emilia Galotti, Miss Sara Sampson*, and *Minna von Barnhelm*.

EKIBASTUZ, a city under oblast jurisdiction in Pavlodar Oblast, Kazakh SSR. Railroad station on the Tselinograd-Pavlodar line, 132 km southwest of Pavlodar. Population, 55,000 (1977). Coal is mined in the vicinity of Ekibastuz. The city has a plant for the production of reinforced-concrete products and a machinery and repair plant for the repair of mining and transport equipment. It also has a meat combine, a milk plant, and a brewery. Among the educational institutions are the general technical department of the Pavlodar Industrial Institute, a mining technicum, and a pedagogical school. [29–1763–5]

EKIBASTUZ COAL BASIN, a coal basin located in Baianul Raion, Pavlodar Oblast, Kazakh SSR. The Pavlodar-Tselinograd main railroad line passes near the basin, as do the Irtysh-Karaganda Canal and the Pavlodar-Karaganda Highway. The basin is confined to an enclosed depression covering an area of 155 sq km. It is 24 km wide and has a maximum width of 8.5 km. The total estimated geological reserves of coal are 10 billion tons.

The Ekibastuz Coal Basin was discovered in 1876. However, intensive geological exploration was begun only in 1940, which established the possibility of mining the coal by the open-pit method. Construction of the first coal pit was begun in 1948; it was put into operation in 1954.

The margin and basement of the basin consist of Lower Devonian volcanogenic formations. The coal-bearing formation of the Lower (Viséan and Namurian) and Middle Carboniferous and the underlying marine sediments of the Middle and Upper Devonian and Lower (Tournaisian) Carboniferous constitute a brachysyncline, bounded on the northeast and southwest by major longitudinal faults. Rocks along the limbs of the brachysyncline are gently bedded (9°–30° degrees), while those in the areas close to the faults are steeply bedded (some even overturned) and complicated by fractures. The lower, unproductive, complex of sedimentary rocks is about 1,000 m thick; the upper, productive, complex reaches a thickness of 1,690 m. The lowermost strata of the coal-bearing formation (the Akkudukian and Ashliarikian suites) contain interlayers of carbonaceous rocks and coals in the upper horizons. The Karagandian suite (to 600 m) and the Suprakaragandian suite (to 390 m), which encompass the central part of the brachysyncline over an area of 74 sq km, contain 11 and nine coal seams, respectively. Three thick, contiguous seams of the Karagandian suite are industrially important: the lower, or third, seam, which is 84–108 m thick (average, 95 m); the middle, or second, seam, which is 33–43 m thick (average, 38 m); and the upper, or first seam, which is 20–25 m thick (average, 22.5 m). Coal seams up to 1.5 m thick alternate with interlayers of sandy-clayey and carbonaceous rocks ranging in thickness from fractions of a centimeter to a few meters. The first and second seams have a more compact structure.

The coals are hard humus coals, with an industrial grade of WCa (weak caking). They have a high ash content, which increases with increasing depth in the coal-bearing cross section and are difficult to enrich. The ash content of coal concentrates with a density of less than 1.8 g/cm^3 ranges from 28 percent (first seam) to 35 percent (third seam).

All the coals in the basin, down to their full depth, are suitable for open-pit mining. Coal extraction in 1975 amounted to 45.8 million tons. The total capacity of the coal sections in 1976 reached 52 million tons. The coals are used as fuel at large power plants (pulverized coal burning) in the Middle and Southern Urals and in Kazakhstan. The Ekibastuz Coal Basin is a key part of the Pavlodar-Ekibastuz Territorial-Production Complex.

K. V. MIRONOV [29–1763–7]

EKIBASTUZ STATE REGIONAL POWER PLANT, a thermal power plant under construction (1980) near the city of Ekibastuz in Pavlodar Oblast, Kazakh SSR. The planned capacity is 4,000 megawatts (eight 500-megawatt units). Ekibastuz hard coal will serve as the fuel. The water supply is of the circulating type, with Lake Zhengel'dy serving as the cooling pond. Power is transmitted over 220- and 500-kilovolt power lines to the integrated power grid of Northern Kazakhstan. [29–1763–6]

EKIMCHAN, an urban-type settlement and the administrative center of Selemdzha Raion, Amur Oblast, RSFSR. Ekimchan is situated on the Selemdzha River of the Amur River basin, 655 km northeast of Blagoveshchensk. [29–1764–2]

EKINCHI (*Äkinchi*; The Plowman), the first Azerbaijani newspaper, published from July 22, 1875, through September 1877 in Baku. *Ekinchi* was founded and edited by G. Zardabi. M. F. Akhundov and Seid Azim Shirvani were among the contributors. Influenced by revolutionary populism, *Ekinchi* championed democratic ideas and denounced tsarist officials, local rulers, and rural extortioners. It promoted enlightened thought and published articles devoted to the development of realistic literature and art. Publication of the newspaper was hindered by the censors, who prohibited it from dealing with political issues after the outbreak of the Russo-Turkish War of 1877–78. *Ekinchi* had a considerable influence on the development of sociopolitical and artistic thought in Azerbaijan.

EKK, NIKOLAI VLADIMIROVICH (real surname, Ivakin). Born June 1 (14), 1902, in Riga; died July 14, 1976, in Moscow. Soviet motion-picture director. Honored Art Worker of the USSR (1973).

In the 1920's, Ekk graduated from the State Higher Workshops and the State Technicum of Cinematography. After working in the Meyerhold Theater he began his career as a film director. His best known films include the first Soviet sound film, *A Start in Life* (1931), and the first Soviet color film, *Grunia Kornakova* (*Nightingale, Little Nightingale*, 1936). Ekk also made a color film version of *Sorochintsy Fair* (1939), the television film *When the Snow Falls* (1962), and the stereoscopic film *The Man With the Green Glove* (1968). He also directed stage plays.

Ekk was awarded the Order of the Red Banner of Labor. [29–1765–3]

EKMAN, VAGN WALFRID. Born May 3, 1874, in Stockholm; died Mar. 9, 1954, in Göstad. Swedish geophysicist. Member of the Royal Swedish Academy of Sciences.

Ekman studied at the University of Uppsala from 1893 to 1896 and at the University of Stockholm from 1896 to 1901. He was a professor at the University of Stockholm from 1910 to 1939.

Ekman's main works dealt with physical oceanography. In 1905, he developed the theory of drift, or wind-driven, currents and gradient currents in the sea. Ekman discovered the rotation of the velocity vector of a current with depth; the theoretical representation of the current distribution is known as the Ekman spiral.

REFERENCE

Kullenberg, B. "Vagn Walfrid Ekman, 1874–1954." *Journal du Conseil permanent international pour l'exploration de la mer*, 1954, vol. 20, no. 2. [29–1770–2]

EKMOLIN (ecmoline), an antibiotic protein preparation derived from sturgeon milt. It exhibits antibacterial properties and prolongs the action of penicillin and other antibiotics (it is a component of *ekmonovotsillin*). [29–1770–3]

EKONOMICHESKAIA GAZETA (Economic Gazette), a weekly newspaper of the Central Committee of the CPSU. Founded in November 1918 as *Ekonomicheskaia zhizn'* (Economic Life), it was originally published by the Supreme Council on the National Economy and the people's commissariats dealing with economic affairs. It became an organ of the Council of Labor and Defense in mid-1921. Beginning in 1931, the newspaper was published by the State Planning Committee (Gosplan) and People's Commissariat of Finance of the USSR, the five Union banks, and the Central Committee of the Union of Financial and Bank Workers.

The newspaper took the name *Finansovaia gazeta* (Financial Gazette) in November 1937. It was not published from the beginning of the Great Patriotic War until 1956, when, in February, it was revived under the name *Promyshlenno-ekonomicheskaia gazeta* (Industrial and Economic Gazette), as an organ of the State Committee on New Technology of the Council of Ministers of the USSR. After being reorganized in June 1960 as a daily organ of the Central Committee of the CPSU, under the name *Ekonomicheskaia gazeta*, it became a weekly in August 1961.

Ekonomicheskaia gazeta publicizes the economic policy of the CPSU and mobilizes the masses for its implementation. The newspaper focuses on economic theory, new developments in economic practice, and socialist competition directed at raising efficiency and the quality of work. Charged with assisting the education of the working people in the area of economics, the newspaper publishes methodological and educational materials on course topics and provides recommendations and advice on management of the system of economic education. It was awarded the Order of the Red Banner of Labor in 1971. Circulation, approximately 850,000 (1978). [29–1814–3]

EKONOMICHESKIE KREST'IANE, a category of peasants in Russia in the second half of the 18th century who were feudally dependent on the state.

Before the secularization of church lands in 1764, the *ekonomicheskie krest'iane* lived on lands held by the Orthodox Church and were known as *monastyrskie krest'iane* (monasterial peasants). In 1764, they were placed under the control of the Collegium of the Economy. The *ekonomicheskie krest'iane* included approximately 2 million peasants settled in various regions of European Russia. They paid *obrok* (quitrent) in cash rather than rendering *barshchina* (*corvée*) or *obrok* in kind; in the 1770's and early 1780's the treasury received more than 1.3 million rubles from them annually.

When the Collegium of the Economy was abolished in 1786, control of the *ekonomicheskie krest'iane* passed to local administrative bodies (financial boards), and the peasants soon ceased to be distinguished from the general mass of state peasants.

EKONOMIKA, a publishing house of the State Committee of the Council of Ministers of the USSR on Publishing, Printing, and the Book Trade. Located in Moscow, it was established in 1963 through the consolidation of three houses: Ekonomizdat, Gostorgizdat, and the publishing house of the Central Cooperative Alliance.

Ekonomika publishes works on general economic problems, the economics of industry and agriculture, planning, material and technical supply and marketing, the organization of national economic management, the economies of the socialist countries, and questions of state trade. It publishes the journals *Planovoe khoziaistvo* (The Planned Economy), *Sovetskaia torgovlia* (Soviet Trade), *Obshchestvennoe pitanie* (Food Service), *Material'no-tekhnicheskoe snabzhenie* (Material and Technical Supply), and *Sovetskaia potrebitel'skaia kooperatsiia* (Soviet Consumers' Cooperative), as well as the bulletins *Novye tovary* (New Products) and *Torgovlia za rubezhom* (Trade Abroad).

In 1979, Ekonomika published 183 titles of books and pamphlets with a total of 6.2 million copies, using approximately 70 million printed sheets. [29–1796–1]

EKONOMIKA I MATEMATICHESKIE METODY (Economics and Mathematical Methods), a scientific journal of the Central Economic Mathematical Institute of the Academy of Sciences of the USSR. Published in Moscow since 1965, the journal is issued six times a year. It deals with problems of the optimal functioning of a socialist economy and with the use of mathematical methods and computer technology for the solution of important problems of planning and administration at the national, sectorial, regional, and plant levels. Results pertaining to the development of the appropriate software are published, along with critiques of bourgeois economic and econometric theories. The journal carries discussions of timely economic problems and provides information on the current literature and on scientific activities. Circulation, more than 6,000 (1978). [29–1801–1]

EKONOMIKA SEL'SKOGO KHOZIAISTVA (Agricultural Economics), a monthly journal of the All-Union Scientific Research Institute of Agricultural Economics of the V. I. Lenin All-Union Academy of Agricultural Sciences. The journal has been published in Moscow since 1926. It deals with Marxist-Leninist agrarian theory and with the economic activity of kolkhozes and sovkhozes. The journal publishes lectures and advice of use in improving the economic education of persons studying in the party system and carries book reviews. Circulation, 70,000 (1978). [29–1805–1]

EKONOMIKA STROITEL'STVA (Construction Economics), a monthly journal of the USSR State Committee for Construction (Gosstroi). The journal has been published in Moscow since January 1959. It is intended for managerial, scientific, and engineering personnel in ministries, departments, construction organizations, design organizations, research organizations, and construction enterprises, as well as for the employees of banks that finance capital construction and for teachers at higher educational institutions and technicums.

Ekonomika stroitel'stva is devoted to problems of increasing the economic efficiency and quality of construction, shortening the time required to put production facilities into operation and to utilize production capacities, refining the system of construction management, and improving cost estimation and price determination. The journal also carries articles on the economics of labor, planning and profit-and-loss accounting in construction, and the economics of both engineering design and solutions to design problems. It encourages innovation and socialist competition by construction workers. Circulation, about 60,000 (1978).

[29–1806–1]

EKSKUZOVICH, IVAN VASIL'EVICH. Born Jan. 26 (Feb. 7), 1882, in Elizavetgrad (present-day Kirovograd); died June 11, 1942, in Leningrad. Soviet theater figure.

Ekskuzovich graduated from the St. Petersburg Institute of Civil Engineering in 1909. In 1918 he was made supervisor of the state academic theaters of Petrograd, and from 1923 to 1928 he managed the state academic theaters of the RSFSR. At the same time he was director of the department of state theaters of the People's Commissariat of Education and of the art division of Glavnauka (Central Administration of Scientific, Scholarly-Artistic, and Museum Institutions). Beginning in 1928, he was engaged in organizational work.

WORKS

Tekhnika teatral'noi stseny v proshlom i nastoiashchem. Foreword by A. V. Lunacharskii. Leningrad, 1930. [29–1902–5]

EKWENSI, CYPRIAN. Born 1921 in Minna. Nigerian novelist who writes in English.

In the novels *People of the City* (1954; Russian translation, 1965) and *Jagua Nana* (1961), Ekwensi criticizes the morality of Nigeria's developing bourgeoisie and reveals the psychological problems of urbanization in Africa. In the novel *Beautiful Feathers* (1963) he appealed to the people to unite. The fate of the people involved in the ethnic conflict that initiated the civil war of 1967–70 are dealt with in the novel *Iska* (1966). The life of the Fula cattle breeders is depicted poetically in the novella *Burning Grass* (1962; Russian translation, 1963).

Ekwensi has also written books for young people and retellings of popular legends.

WORKS

Lokotown and Other Stories. [No place] 1966.
Restless City and Christmas Gold. London, 1975.

S. P. KARTUZOV [29–1745–4]

EKZEKUTOR, a marshal of the court (in prerevolutionary Russia, a civil servant) who managed an institution or office.

[29–1754–1]

ELAT (also Elath), a city in Israel. Population, 13,000 (1972). Elat, a port on the Red Sea, is connected by highway with Tel Aviv. Its industries include diamond-cutting and jewelry-making. The manufacture of cement and food products (mainly fish products and wine) is also important. Nearby there are deposits of copper, at Timna, and semiprecious stones. Oil pipelines lead from Elat to Haifa and through Ashqelon. There is commercial fishing. [29–1708–2]

ELATERIDAE (click beetles), a family of beetles. The body is elongated and the short legs have tarsi with five segments. The body ranges in length from 2 mm to 50 mm, although it most commonly measures 7–20 mm. The antennae have 11–12 segments and are serrated or pectinate, rarely filiform. The prothorax has a process that is directed back into a special cavity in the mesothorax. With the aid of this mechanism beetles that fall on their backs are able to turn over by jumping up with a clicking noise. The wings are usually well developed.

The family embraces approximately 10,000 species, more than 500 of which are found in the USSR. The ubiquitous insects live on plants, on which they feed. The larvae, which are called wireworms, develop in the soil and in rotting wood and feed on disintegrating plant remains, living roots, or the larvae of other insects. The larvae of *Agriotes, Selatosomus*, and other genera are agricultural pests, harming germinating seeds or gnawing into the tillering crown of cereal grasses until the plant weakens and dies. They are also harmful to forest plantings.

O. L. KRYZHANOVSKII [29–1585–3]

ELEKTROKHIMPROM CHIRCHIK PRODUCTION ASSOCIATION (until 1975, the Chirchik Electrochemical Combine), a unit of the Soiuzazot All-Union Association of the Ministry of the Chemical Industry, located in the city of Chirchik, Tashkent Oblast. It manufactures ammonium nitrate, urea, ammonia water, liquid ammonia, nitric acid, various catalysts, and other products.

The combine was one of the first chemical enterprises in the USSR to be designed by Soviet engineers and outfitted with equipment manufactured in the Soviet Union. Construction was begun in 1936. The first product to be manufactured (November 1940) was ammonium nitrate. The second stage of production facilities was put into service in 1944. It manufactured ammonia by gasifying local coal; since 1961 it has produced ammonia by cracking natural gas from the Bukhara gas fields. A catalyst production plant was put into service in 1949, and a urea production shop in 1964. The main shops have been enlarged and rebuilt several times.

Between 1940 and 1975, production volume increased by a factor of 30, and labor productivity rose by a factor of 9.5. The increases were achieved mainly by introducing new technologies and inventions and by following the recommendations of efficiency experts. The total annual production of the association is valued at 100 million rubles. Products are exported to 12 foreign countries. The association was awarded the Order of Lenin in 1971 and the Order of the Red Banner of Labor in 1943.

[29–619–1]

EMERGENCY, STATE OF, a special legal state declared in a country for a given period of time to cope with extraordinary circumstances and permitting the use of special measures to maintain order.

A state of emergency usually involves the establishment of agencies with special powers, the introduction of extraordinary security measures, and the extension of the competence of administrative bodies to include the right to suspend existing legislation.

In capitalist countries, a state of emergency in the form of martial law or a state of siege is usually proclaimed to counter a drastic intensification of the class struggle or an upsurge of a revolutionary or national liberation movement. It is also declared in the event of a war or a natural disaster. In Chile, for example, the military-fascist junta of Pinochet, in violation of the constitution, declared a state of internal war and then a state of siege in order to justify a reign of terror and lawlessness and the repression of Chilean patriots without inquest or trial.

The Constitution of the USSR (art. 121, par. 15) provides the Supreme Soviet of the USSR with the right to declare martial law in specific areas or throughout the entire country in the interests of the defense of the USSR. [29–691–1]

EMERGENCY BUDGET, a schedule of state revenues and expenditures that is regarded as an addition to, rather than a formal part of, the ordinary state budget and is approved by a special procedure differing from that for the ordinary budget.

In capitalist countries of the era of premonopoly capital, emer-

gency budgets were introduced sporadically, chiefly in wartime. In the present stage of the general crisis of capitalism, emergency budgets, which have become a recurring phenomenon, are used to conceal or minimize chronic budget deficits, to help provide funds for military appropriations and strategic construction projects, and to service the national debt. They exist in several capitalist countries in various forms, including supplementary budgets and budgets comprising special receipts and expenditures. The USSR does not have emergency budgets. [29–692–1]

EMERGENCY LEGISLATION, extraordinary or exceptional laws that become effective in a state of emergency and that give the government extraordinary powers, such as the right to establish legal norms the executive is ordinarily not entitled to establish and the right to suspend individual laws or certain of their norms, including constitutional guarantees. Emergency legislation is widely used by imperialist states to combat revolutionary and national liberation movements. It was employed to establish fascist regimes in Germany, Spain, and Portugal and the dictatorship of Pinochet's military-fascist junta in Chile. In the 1950's the Federal Republic of Germany passed a number of antidemocratic emergency laws directed against progressive forces; for example, the right to choose and practice a profession was limited, the right to strike was revoked, and freedom of movement was restricted. [29–690–4]

EMERGENCY TAX, a mandatory payment made to the state and exacted only under special circumstances, such as the advent of war.

Emergency taxes are levied either by imposing new taxes or by raising existing tax rates. They were widely used in Russia and Great Britain during World War I and in Great Britain, the USA, and Germany during World War II. In capitalist countries the working people pay the bulk of emergency taxes; the capitalists usually try to avoid such taxation. When the monopolies have to pay emergency taxes, the expenditure is recovered through a faster rate of depreciation or through overt or covert subsidies granted by the state—for example, military orders may be filled at higher prices. Thus, between 1945 and 1955, American monopolies were repaid $25.7 billion, which amounted to over half of the taxes they paid in World War II.

Emergency taxes have been used in the USSR as a way of attracting capital from the population to finance extraordinary state expenditures. In 1918, during the Civil War, a one-time emergency revolutionary tax was imposed on the well-off strata of the population, raising 10 billion rubles. A tax was collected from all citizens in 1922 to help famine victims, and a one-time tax was introduced in 1924 to counter the effects of a crop failure. A war increment imposed on income and agricultural taxes in 1941 was replaced in 1942 by a war tax, which was abolished in 1946. [29–691–2]

END-MEASURING INSTRUMENT, any of a certain class of instruments that are used to measure or lay out inside and outside dimensions. An end-measuring instrument consists of two measuring surfaces, which are usually called jaws. A dimension is determined between the two measuring surfaces. One of the surfaces constitutes the base of a single unit that includes a rule, or a graduated bar; the other surface is on a head that slides along the rule. The rule is divided into millimeters, and a vernier scale is installed or engraved on the sliding head. To increase their reliability, end-measuring instruments are made of materials that have a high abrasion resistance and are not subject to corrosion, such as hardened steels. In addition, the measuring surfaces are chrome-plated or are reinforced by a hard alloy. Plastic end-measuring instruments are also used.

In the USSR, several types of end-measuring instruments with readings in 0.05 or 0.1 mm are manufactured in several standard sizes. The manufacture of end-measuring instruments with readings in 0.02 mm has been discontinued. Depending on their purpose and design features, end-measuring instruments are classified as vernier calipers, height gauges, height-and-depth gauges (*see* DEPTH GAUGE), or gear-tooth calipers.

The vernier caliper (Figure 1) is the most widely used end-measuring instrument. The first vernier calipers appeared in the late 18th century in London, although wooden caliper rules without verniers were used as early as the 17th century. Three types of vernier calipers are manufactured in eight standard sizes; the types differ in design and in the number of measuring jaws. For measurements of up to 400 mm, the jaws may be extended from the zero reading. For larger dimensions, the zero point of a measurement does not coincide with the zero mark.

Vernier calipers with an instrument range extending from 0 to 125 or 150 mm and with readings in 0.1 mm have two sets of jaws (Figure 1,a) as well as a rule depth gauge for measuring such dimensions as the depth to a shoulder or the depth of a groove or a hole. The lower jaws are used to measure outside dimensions; the upper jaws, inside dimensions.

Vernier calipers with an instrument range extending up to 250 or 160 mm and with readings in 0.1 or 0.05 mm (Figure 1,b) also have two sets of jaws. However, the lower jaws are used for both outside and inside measurements, while the upper jaws are employed to lay out or measure outside dimensions inside narrow shallow grooves and holes. The upper jaws may be used to scribe parallel lines, circles, and other elements of the shape of a part to be machined (*see* LAYOUT TOOL). In such vernier calipers, the jaws for measuring inside dimensions have cylindrical surfaces. The size of the jaws when closed is usually 10 mm; the jaw size is stamped on a surface that is not used for measurement and is added to the reading when inside dimensions are measured.

Vernier calipers with an instrument range extending to an upper limit of 400 to 2,000 mm have a single set of jaws that is similar in design to the lower jaws of the caliper shown in Figure 1,b. The last two types of vernier calipers have a micrometer feed, which is used mainly in layout work, for the more precise determination of a dimension. The readings on such calipers are in 0.1 mm.

In contrast to a vernier caliper, a height gauge (Figure 2) has a base rather than a fixed jaw. Measurements are made from the bottom of the base, which corresponds to the zero reading on the scale. The sliding head is equipped with a holder rather than a movable jaw. For layout work, a stylus or a scriber is attached to the holder; for measurement, a special set of measuring jaws or a bracket for fastening a meter—such as a dial indicator—is attached to the holder. Height gauges are usually employed in layout work on plates. In such work, the gauge is mounted on the plate together with the workpiece to be laid out or measured. On ▪ workpiece to be laid out, lines are scribed with a scriber when the height gauge is moved over the surface of the plate. Height gauges are manufactured in six standard sizes with readings in

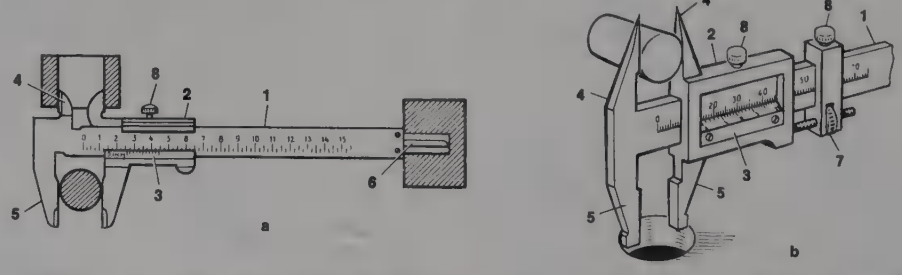

Figure 1. Vernier calipers: (1) graduated bar, (2) sliding head, (3) vernier, (4) upper jaws, (5) lower jaws, (6) rule depth gauge, (7) micrometer feed, (8) setscrews

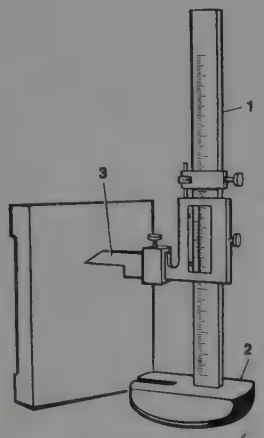

Figure 2. A height gauge: (1) graduated bar, (2) base, (3) scriber

0.05 mm for an instrument range extending to an upper limit of 400 mm or with readings in 0.1 mm for instrument ranges extending to an upper limit of 400 to 2,000 mm.

A gear-tooth caliper, which is a combination of a height-and-depth gauge and ▪ vernier caliper, is designed to measure the thickness of gear teeth. The vertical rule of a gear-tooth caliper is used to determine the depth of a tooth from the tooth's tip, where the tooth thickness is measured. The horizontal caliper is used for the direct measurement of the tooth thickness. Gear-tooth calipers with readings in 0.05 mm are manufactured in two standard sizes for the measurement of the tooth thickness of gears with a modulus of up to 36 mm. Owing to the rapid abrasion of their tips and to their relatively low accuracy, gear-tooth calipers are being replaced to an increasing extent by displacement tooth gauges and tangent tooth gauges.

N. N. MARKOV [29–1451–4]

ENRICHMENT SYSTEM, a set of devices in the carburetor of an internal-combustion engine. An enrichment system is used to enrich the fuel-air mixture when the throttle valve is wide open or nearly wide open. It enhances the economical operation of an engine. [29–1787–1]

ENTRENCHING TOOLS, regulation-issue military tools used in manual engineering work. Two general classes are distinguished: entrenching tools that are part of a soldier's personal gear and those that are part of the standard equipment of a vehicle. The first class consists simply of a small shovel, although before the Great Patriotic War of 1941–45 it also included a small ax and a pick-mattock. The small shovel is included in the field equipment issued to sergeants and to enlisted men of lower rank and is used primarily for digging trenches. Entrenching tools of the second class, issued to motor pools and convoys, are part of the standard equipment of fighting and transport vehicles and comprise a long-handled shovel, a broadax, a pick-mattock, and ▪ crosscut saw. They are used for such work as preparing field positions and billeting areas. [29–840–2]

ENVIRONMENTAL PHYSIOLOGY, a branch of physiology that studies the dependence of human and animal functions on conditions of life and activity in different physicogeographical zones, during different times of the year and day, and at different phases of the moon and tidal rhythms. Environmental physiology, which reveals the physiological bases of adaptations to natural factors, is closely tied in with ecology, chronobiology, the physiology of aging and evolution, the physiology of farm animals, and ethology; when the subject of study is man, it is also closely related to climatophysiology and the physiology of work and sports. All levels of physiological integration are studied: supraorganismic (populational), organismic, organic and systemic, and cellular and subcellular (molecular). In human environmental physiology, clinical, chemical and electrophysiological laboratory methods, such as radiotelemetry, are used.

The development of adaptations is studied by isolating an organism from individual environmental factors (controlled cultivation and rearing) and by comparing the parameters of physiological reactions in species that are taxonomically similar but that have different ecological specialization, such as arctic, tropical, desert, terrestrial, and semiaquatic organisms with different levels of muscle activity. In research on sensory systems, signalization, echolocation and ranging (bats, birds, fish), and chemical links (pheromones) between organisms, environmental physiology depends upon biophysical and biochemical data.

Environmental physiology enables man to forecast the mass multiplication of pests (rodents, insects) and acclimatize beneficial animal species; it also makes possible the regionalization of farm animals by breeds and the acclimatization of man to new climatic regions as new areas are developed (high latitudes, mountains, deserts). It studies the physiological characteristics that determine the course of the adaptive reactions in various animals inhabiting particular regions (*see* LIFE FORM). At various phylogenetic levels, such general characteristics include mechanisms for the conservation of water in desert animals, osmotic control in desert, semiaquatic, and aquatic organisms, and the energy flow in organisms and their individual systems (high in northern latitudes and low in arid and tropical zones).

In the USSR, research in environmental physiology has been conducted since the 1930's, including the study of thermoregulation (A. D. Slonim, O. P. Shcherbakova), adaptation to hot and cold climates (A. Iu. Iunusov, I. A. Izrael'), adaptation to mountainous conditions (A. G. Ginetsinskii, N. N. Sirotinin, M. M. Mirrakhimov), adaptation to environments with ▪ variable gaseous composition (E. M. Kreps, Z. I. Barbasheva), and mechanisms of hibernation (N. I. Kalabukhov). The ecological approach was also used in the study of the nervous system (D. A. Biriukov) and the genetics of behavior (D. K. Beliaev, M. E. Lobashev). Beginning in the 1950's, research in environmental physiology expanded in connection with the development of new territories, such as the arctic, subarctic, deserts, and mountainous regions; bases have been established at mountain, desert, and marine stations, and laboratories have been set up at wildlife sanctuaries. A pressing need is developing to investigate the effects of noise, vibration, and temperature factors on the human body as a whole and on the function of individual organs (V. V. Parin, A. S. Troshin).

Various aspects of environmental physiology have been studied abroad since the 1920's, including the comparative physiology of respiration and muscle activity (A. Krogh), the effect of decreased air pressure on the respiratory function of the blood (J. Barcroft), adaptation to low temperatures (C. L. Prosser, T. H. Bullock, and P. F. Scholander; USA), the adaptation of animals to desert life (K. Schmidt-Nielsen; USA), and the physiology of human work under extreme arctic and desert conditions (O. G. Edholm; Great Britain). Since the 1970's, the problems of environmental physiology have become closely linked with those of conservation. (*See also* PHYSIOLOGY.)

ÉPÉE, a fencing weapon consisting of a flexible steel blade with a protective guard and handle. The blade has a three-sided section (the maximum width of a side is 24 mm) that grows thinner toward the point, where there is a tip with a movable electrical con-

tact. The overall length is no more than 110 cm (the blade itself is no longer than 90 cm), the diameter of the guard is 135 mm, and the weight ranges up to 770 g. Only men engage in fencing competition with the épée. [29–1384–2]

EQBAL, ABBAS. Born 1897; died Feb. 11, 1956, in Rome. Iranian historian and philologist.

Eqbal graduated from the University of Paris in 1926. Together with M. Qazvini, he founded the literary and historical journal *Yadegar* (Monument). He wrote on medieval and modern Iran. Eqbal was responsible for the publication of many medieval sources and the memoirs of various Europeans who had visited Iran.

EQUANT, an auxiliary point in the Ptolemaic system (the point E in the figure), introduced by Ptolemy to match observed planetary motions with motions previously calculated with deferents and epicycles.

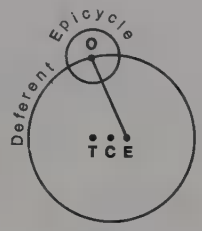

Figure 1

Describing the motion of the planets with circles and constant angular velocities, Ptolemy placed the earth (T) outside the center of the deferent (C). He assumed that the center of the epicycle (O) of a planet moved nonuniformly along the deferent, but in such a manner that the motion seemed uniform to an observer located at the equant, which was symmetric to the position of the earth relative to the center of the deferent. [29–1737–5]

EQUATIONAL DIVISION, a method of reproduction in animal and plant cells; a rarely used synonym for mitosis. As a result of equational division the initial number of chromosomes in the cell is preserved. Equational division is contrasted with reduction division, or meiosis, as a result of which the number of chromosomes in the cell is halved. [29–1745–3]

EQUATORIAL, a lens or mirror telescope on a parallactic, or equatorial, mounting (*see* TELESCOPE MOUNTING). A clock mechanism rotates the telescope around a polar axis at a rate of one rotation per 24 sidereal hours, so that the celestial object being observed, which moves because of the apparent diurnal rotation of the celestial sphere, remains in the field of view of the telescope. Graduated circles with measuring devices are secured to the axes to direct the telescope at the celestial object according to its hour angle and declination and to enable the approximate determination of its coordinates. Auxiliary astronomical tubes mounted on the primary one, called the finder and the guide, are used to locate the necesssary object and to keep the instrument directed at it during photography.

Equatorials may be visual (equipped with an ocular that has a micrometer for differential measurements) or photographic (with plateholders). (*See* ASTRONOMICAL INSTRUMENTS AND DEVICES.) [29–1738–4]

EQUATORIAL AIR, air masses that form in the equatorial zone or flow from it to the higher latitudes (for example, the air of the summer monsoon over the northern part of the Indian Ocean). Equatorial air is separated from tropical air by the intertropical zone of convergence or tropical front. [29–1743–7]

EQUATORIAL BELT, a geographic belt of the earth located on both sides of the equator between 5°–8° N lat. and 4°–11° S lat., between the subequatorial belts. Some scientists include the equatorial belt in the tropical belt (*see* TROPICAL BELT). The equatorial belt is characterized by the prevalence of equatorial air masses, weakly expressed sectors on the continents, and the presence of *gilea*-type forests on the plains of the latitudinal zone and zones of *gilea* and paramo vegetation in the mountains (*see* GILEA).

The climate is caused by the large influx of solar energy. The radiation balance on land is 70–80 kcal/cm^2 per year, sometimes reaching 90 kcal/cm^2. The average monthly temperatures in the lowlands are 24°–28°C; the annual variation in the average monthly temperature is 2°–3°C, the lowest on the earth. The equatorial belt is characterized by the presence of the equatorial low, which is linked to the intertropical zones of convergence of the tradewinds, in which air masses rise, moisture condenses, and abundant precipitation falls (1,500–3,000 mm a year, up to 10,000 mm on the windward slopes of mountains). Precipitation almost always exceeds evaporation, and moisturization is excessive. The rivers have abundant water, with relatively small fluctuations in the flow rate, except those rivers whose basins lie in other geographic belts. The equatorial parts of the continents typically have no seasonal rhythms, but all natural processes are highly active. Thick weathering crusts are characteristic. Acidic red-yellow ferralitic (lateritic) soils with total humification of dead plant matter and rapid mineralization of organomineral complexes predominate. These soils are poor in bases and humus (2–3 percent) and rich in the hydroxides of iron and aluminum. The vital activities of microorganisms and small animals in the soil and on the soil surface are extremely vigorous. When the forests are cleared and the ground plowed, given the high temperatures and drainage conditions, the soils of the equatorial belt lose their fertility quickly.

The humid equatorial evergreen forests (*gilea*, the Brazilian *selva*) are distinguished by the different times of periodic functions of individual plants in the absence of seasonal aspects within the community as a whole, the dense tree growth, the unusual wealth and age of the species composition, the abundance of lianas and epiphytes, and the high productivity of the aboveground biomass (40–50 tons/ha, up to 100). Mangrove thickets are common along the sea and ocean. Economically useful plants abound, such as rubber plants (including *Hevea*), the cacao tree, the breadfruit tree, the cotton tree (*Ceiba*), various palms, and trees with valuable wood. The animals that inhabit the equatorial forests are adapted to life in the trees, for example, monkeys, lemurs, sloths, and cats. Common ground animals are the tapirs, rhinoceroses, peccaries, and hippopotamuses. Birds, reptiles, and insects are numerous. Two subzones are identified in the *gilea* zone: the continually humid equatorial forests and the equatorial forests with a short dry season (two to three months). The latter occur in the parts of the belt farthest from the equator and in the eastern sectors, which come under the influence of the continental tradewinds. A mixture of deciduous species (losing their leaves in the dry season) occurs in the forests, as well as patches of savanna, formed primarily as a result of human economic activities. Some of the land, mostly in the more accessible marginal parts of the equatorial forest, is planted with subsistence and plantation crops. The chief occupations of the population in the continually humid equatorial forest subzone are logging, fishing, hunting, and primitive subsistence farming.

The uniformity of annual temperatures and precipitation is maintained in the mountains of the equatorial belt. Owing to the drop in temperature with elevation, the change in the nature of precipitation, the greater thinness of the air, and the increase in insolation, three zones of humid mountain equatorial forest are identified below 3,000–3,500 m—tierra caliente, tierra templada, and tierra fria. Above this elevation is a belt of high-mountain equatorial meadows called paramos, which at 4,300–4,800 m gives way to the nival zone.

In the ocean regions, the equatorial belt is characterized by an even higher radiation balance (up to 120 kcal/cm^2 per year), a thicker cloud cover, abundant rainfall, and mild winds and calms. The surface waters are slightly less saline (about 34 parts per thousand) than the average ocean waters and are rich in plank-

ton. In connection with the characteristics of circulation of the atmosphere and water, the equatorial belt is clearly delineated in the western sectors of the Pacific and Atlantic oceans; in the eastern sectors it is clearly delineated only north of the equator, and in the Indian Ocean, only in the central and eastern sectors.

E. N. LUKASHOVA [29–1744–1]

EQUATORIAL CHANNEL, a strait in the southern Maldives, between Suvadiva Atoll and Fua Mulaku Island. The Equatorial Channel is 85 km wide, with depths to 2,421 m. It flows westward in winter and eastward in summer at a velocity of approximately 2 km per hour.

[29–1745–1]

EQUATORIAL CLIMATE, the climate in the zone of the humid forests of the equatorial belt, characterized by mild winds, very small annual temperature fluctuations (24°–28°C at sea level), and abundant precipitation (1,500–5,000 mm a year), which occurs more or less evenly throughout the year.

[29–1743–8]

EQUATORIAL FOREST ZONE, a natural zone of the equatorial belt, in whose natural landscapes forests predominate (*see* RAIN FORESTS and GILEA). The zone encompasses primarily the lowlands on both sides of the equator, including the Amazon River basin, Equatorial Africa, the islands of the Malay Archipelago, and New Guinea. Characteristic features of the equatorial forest zone are a relatively constant length of day, a lack of seasonal rhythms in the development of nature, an equatorial climate, and a thick weathering crust. Dense evergreen forests with a rich species composition grow in the equatorial forest zone, as well as many palms, lianas, and epiphytes. Deciduous species are intermixed in the forests of the outer parts of the zone.

[29–1745–2]

EQUATORIAL GUINEA (Republic of Equatorial Guinea [República de Guinea Ecuatorial]), a country in Central Africa, on the Gulf of Guinea. It comprises the mainland territory of Río Muni and the islands of Bioko (formerly Fernando Póo), Corisco, and Palagu (formerly Annobón). Area, 28,000 sq km. Population, 320,000 (1976). Río Muni borders on Cameroon in the north and Gabon in the east and south. The capital is the city of Malabo. Equatorial Guinea is divided into two provinces.

Constitution and government. Equatorial Guinea is a republic. As a result of the military coup of Aug. 3, 1979, all legislative and executive power rests with the Supreme Military Council. The chairman of the council is also the chief of state.

Natural features. Equatorial Guinea is situated near the equator in the natural region of Lower Guinea. Río Muni is a highland, with elevations of 600–900 m; the maximum elevation is 1,500 m. A low-lying strip of land extends along the coast. The climate is equatorial and is humid throughout the year. The average monthly temperature is 24°–28°C, and annual precipitation exceeds 2,000 mm, reaching 2,500 mm on the islands. The country has a dense network of broad rivers, which have many rapids and can be navigated only in their lower courses. The principal river is the Mbini.

Flora is represented by evergreen equatorial rain forests on red-yellow lateritic soils. More than 150 valuable wood species grow in the forests, including oil and coconut palms, Persian parrotia, and okume. The fauna of Equatorial Guinea is abundant and varied.

Population. More than 90 percent of the population of Equatorial Guinea is made up of members of the Fang and Bube (Bubi) peoples, who belong to the northwestern Bantu. The Fang inhabit primarily continental Guinea (Río Muni); the Bube constitute the indigenous population of Bioko. The coast of Río Muni is inhabited by a group of tribes known collectively as the *playeros*, who include the Benga, Balenge, Bujeba, Kombe (Combe), and Indowe. Although the dominant religion is Roman Catholicism, there are some Protestants, and part of the population still adheres to traditional forms of worship. The official language is Spanish. Equatorial Guinea uses the Gregorian calendar.

The average annual population increase between 1970 and 1974 was 1.7 percent. The economically active population numbers 103,000, of whom 78.7 percent are employed in agriculture (1970). The average population density exceeds 11 persons per sq km. The most populous regions are Bioko and the coastal area of Río Muni. The main cities are Malabo, with 45,000 inhabitants (1975), and Bata.

Historical survey. The island of Bioko was discovered by the Portuguese in the early 1470's and named after its discoverer, the navigator Fernão do Po. In 1778 it passed to the Spanish, who did not permanently establish themselves on the island until 1843. At the same time, the Spanish fought with the local population for control over continental Guinea—Río Muni. In 1900, borders between the Spanish and French possessions on the mainland were drawn.

The Spanish colonialists cruelly exploited the local population, drove it from the most fertile lands, and introduced a system of forced labor. To deal with the labor shortage, the Spanish plantation owners recruited African workers from other African countries, chiefly Nigeria. For many years the people of Equatorial Guinea fought to liberate themselves, a struggle that intensified in the late 1930's; in 1937, 1947, and 1959 mass demonstrations demanding independence took place. The first political parties, formed in 1959, devoted their energies to achieving national independence. In December 1960 Nigerian workers on Fernando Póo struck in protest against the tyrannical rule of the Spanish plantation owners.

In an attempt to disguise the colonial regime, Spain announced in 1960 the abolition of colonial status and the transformation of Fernando Póo and Río Muni into an overseas province. In January 1964 the regions were granted "internal autonomy," and an autonomous government council and an autonomous general assembly were created in the colony. Four years later, the growth of the national liberation movement forced Spain to grant political independence to Spanish Equatorial Guinea. The independent Republic of Equatorial Guinea (REG) was proclaimed on Oct. 12, 1968.

The United National Party was founded in 1970 and renamed the United National Workers' Party in July 1972. All previously existing political parties and mass organizations were dissolved. According to the new constitution of the Republic of Guinea, adopted in July 1973, the party "develops general policy for the nation" and sets the task of "abolishing once and for all the exploitation of man by man." The role of the state in the economy is increasing. As a result of a military coup in August 1979, all power passed to the Supreme Military Council, which banned all political activity in the country.

In foreign policy, the REG has declared itself a nonaligned nation. It is a member of the UN and the Organization of African Unity. Diplomatic relations between the USSR and the REG were established on Dec. 7, 1968, and the two countries have signed agreements on economic and technological cooperation, cooperation in ocean fishing, and trade.

Political parties. The United National Workers' Party (Partido Unico Nacional de los Trabajadores, or PUNT) was founded in 1970 and called the United National Party until July 1972. It is the only party in the country, and, in accordance with its charter, it unites the entire adult population of the REG. A youth and a women's organization function under the auspices of PUNT.

Economic geography. Equatorial Guinea is an agricultural country, with two main economic sectors: the state sector and the private capitalist sector. In addition to encouraging private enterprise and attracting foreign capital, the government is committed

to establishing state intervention in the national economy. A decree adopted in 1974 gave the state control over plantations abandoned by the Spanish. According to a law on foreign investments passed in 1975 the state must control more than 50 percent of the capital in any company. The 1973 constitution introduced a state monopoly over foreign trade; domestic trade is also in the hands of the state. A national monetary system and a central national bank have been created.

AGRICULTURE. The economy of Equatorial Guinea is based on agriculture. The main branches are land cultivation, which produces chiefly for export, and timber felling. Shifting hoe farming predominates in Río Muni, and a plantation economy predominates on the island of Bioko. The cultivated land takes up more than 150,000 hectares (ha), including 90,000 ha in Río Muni (approximately 4 percent of the mainland area) and more than 60,000 ha on Bioko (25 percent of the island's area).

The principal export crops are cocoa and coffee. Cocoa is grown primarily on Bioko, which produces 90 percent of the harvest; cocoa plantings occupy 52,000 ha, including 42,000 ha on Bioko, which produced a harvest of 12,000 tons in 1976. Coffee, of which 6,000 tons were harvested in 1977, is grown mainly in Río Muni, which accounts for more than 80 percent of the total harvest. Oil palms produced 2,000 tons of seed kernels in 1976. The country's 3,000 ha of banana trees yield a harvest of 12,000 tons. In addition to yams and other vegetables, crops grown for local consumption include rice, peanuts, sugarcane, and citrus fruits.

Animal husbandry is poorly developed. In 1975 there were 4,000 head of cattle, 32,000 sheep, and 8,000 goats. Commercial fishing, with a catch of 2,000 tons in 1976, and shrimping are of local importance. Río Muni is the principal timber region; 100,000 cu m were cut in 1975, primarily valuable wood species. Also of some economic importance are the fruit of wild oil palms and the sap of rubber trees.

INDUSTRY. Industry, which is little developed, is represented mainly by small cottage enterprises. Small plants for the production of palm oil produced 2,400 liters in 1976; there are also sawmills and wood-products enterprises. The output of electric power was 15.8 million kilowatt-hours in 1970.

TRANSPORTATION. Equatorial Guinea has 1,200 km of roads, including 400 km of tarred roads. There is maritime navigation. The country's chief ports are Malabo, Bata, and Luba.

FOREIGN TRADE. In addition to cocoa, which accounts, on the average, for 40 percent of all exports, Equatorial Guinea exports coffee (20 percent of all exports), lumber, bananas, and oil-palm products. The country imports petroleum products, cement, textiles, food products, and other necessary commodities. The monetary unit is the ekuele. S. Iu. SOROKINA

Education. Education is compulsory for children from six to 14, and all educational institutions are state-run. There is little preschool education; elementary education continues for six years. In the 1973–74 school year more than 35,900 pupils were enrolled in elementary schools. Secondary education lasts four years at the partial secondary school and six years at the full secondary school. In the 1972–73 academic year more than 4,700 students were enrolled in the secondary schools. In that same year, 586 students attended vocational-technical schools, which have a course of instruction lasting three and one-half years. Elementary school teachers are trained at two three-year pedagogical schools, which had more than 200 students in the 1972–73 academic year. Citizens of Equatorial Guinea must go abroad for higher education. There is a library in Malabo. V. Z. KLEPIKOV

Press and radio. Until mid-1975, Equatorial Guinea had two newspapers which were state owned and published in Spanish: *Unidad de la Guinea Ecuatorial* (founded 1937), a daily newspaper with a circulation of 1,000, and *Libertad* (founded 1970), a weekly newspaper with a circulation of 800. In mid-1975 publication of both papers was suspended because of national economic difficulties. At the end of 1975 the state-owned daily *Diario de la Guinea Ecuatorial* and *Guinea Ecuatorial Revolucionaria al Dia*, issued irregularly, first appeared; publication of *Libertad* was resumed.

The country's two state-owned radio stations are Radio Malabo, located in the city of Malabo, and Radio Ecuatorial, located in the city of Bata. Broadcasts are in Spanish and Fang. There is a television station in Malabo.

EQUATORIAL (NEGRO-AUSTRALOID) RACE, the collective name of the Negroid and Australoid races in the tropical zone of Africa, South and Southeast Asia, Oceania, and Australia. Representatives of the Equatorial race are characterized by curly or wavy hair, dark skin, hair, and eyes, prognathism, a wide nose, and thick lips. Some anthropologists consider the Negroid and Australoid races to be genetically related and combine them into one large race, while others regard them as having developed convergently in the process of adaptation to the ecological conditions of a hot climate. Dark coloration of the skin could possibly provide protection from the harmful effects of intense sunlight, as could curly hair, which forms a natural protective "cap" on the head. Thick lips and wide nostrils may have had adaptive significance for high evaporation of moisture through the mucosa. [29–1742–3]

EQUATORIAL PLATE, in a dividing cell, the arrangement of the chromosomes at the same distance from both poles. The equatorial plate is formed during the metaphase stage of cell division. At this stage it is difficult to distinguish separate chromosomes, but in aggregate they have the appearance of a plate. When, however, the cell is viewed from the poles, the chromosomes in the equatorial plane of the spindle appear in the form of a star. After the formation of the equatorial plate, the daughter chromosomes separate and migrate to opposite poles. [29–1742–4]

EQUATORIAL UNDERCURRENT OF THE INDIAN OCEAN (also Tareev current), a deep current in the Indian Ocean that flows eastward along the equator. It is 220–230 km wide and has an average velocity of 20–30 cm/sec; the maximum velocity is 100 cm/sec, occurring in the western part of the ocean at depths of 100–125 m. The current is most developed during the winter in the northern hemisphere, when the surface Monsoon Current is flowing in the opposite direction. The current was discovered in 1959–60 through expeditionary studies on the Soviet ship *Vitiaz'*. It was named in honor of the Soviet oceanographer B. A. Tareev (1931–72) in 1974. [29–1743–3]

EQUIDENSITOMETRY, a method of photometric measurement without instruments, widely used in astronomical photometry, spectrochemical analysis, X-ray diffraction analysis, and interferometry.

In equidensitometry, a halftone photographic image of an object is converted into an image consisting of lines made up of geometric points at which the value of the optical density does not exceed some narrow range. In the first applications of the technique, a negative of the object and a positive obtained from the negative were superimposed, and a combined image was then printed in transmitted light. The combined printed image was a set of curved lines of equal density (called equidensities, which gave the technique its name). Later, the method was replaced by direct printing from the negative and partial reversal of the positive by means of the Sabattier effect (*see* PHOTOGRAPHIC EFFECTS). In the 1960's and 1970's a third variant was used, in which the printing was done on special double-layer photographic materials.

A. L. KARTUZHANSKII [29–1749–3]

EQUIDISTANT CURVE. The set of the ends of equal segments laid off in a fixed direction along the normals to a given plane curve L is known as an equidistant curve of L. For example, an equidistant curve of a circle is a circle. In Lobachevskian geometry an equidistant curve of a straight line—that is, the locus of points at a given distance from the line—is called an equidistant curve (with that line as base) or, less frequently, a hypercycle. In Euclidean geometry an equidistant curve of a straight line is a straight line. [29–1749–4]

EQUIPLAIN, a denudation surface occurring as a result of cirque denudation. It forms with the development of cirques on both slopes of an elevation. The walls of the cirques retreat toward one another, then connect, forming a sharp, crested divide. Finally they disintegrate completely and the bottoms of the cirques join. The term "equiplain" is sometimes used for planation surfaces of permafrost-solifluction origin.

[29–1749–6]

EQUIPOTENTIAL SURFACE, a surface all of whose points have the same potential. For example, the surface of a conductor in electrostatics is an equipotential surface. In a force field the lines of force are normal, or perpendicular, to an equipotential surface.

[29–1749–7]

EQUIVALENCE, PRINCIPLE OF, in economics, the principle according to which a given amount of labor in one form is exchanged for an equal amount of labor in another. The principle of equivalence constitutes the internal basis of exchange proportions when exchange corresponds to the expenditure of socially necessary working time.

In the socioeconomic formations characterized by commodity production, the operative principle is that of value equivalence; where commodity production is absent (that is, under the primitive communal and communist modes of production), it is the principle of labor equivalence that is operative. The principle of value equivalence evolved in conjunction with the growing social division of labor and increasing exchange of commodities. In the initial stages of commodity exchange, when exchange transactions were sporadic and exchange proportions were random in character, the principle of equivalence lacked regulatory effect. It was only when exchange between individual private producers became a constantly repeated social act, representing an essential element of reproduction, that the prerequisites were created for the equivalence principle.

With the expansion of commodity-money relations and the establishment of the system of commodity production, in which the producers' social interrelations take place exclusively through the market, "it is not exchange of commodities which regulates the magnitude of their value; but, on the contrary, it is the magnitude of their value which controls their exchange proportions" (K. Marx, in K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 23, p. 73). With the advent of money, the value of commodities acquires a uniform social form of expression, making it possible to assess and account for expenditures of abstract labor in the use value of the universal equivalent; the proportions of production and exchange are regulated by the law of value, the equivalence principle being a manifestation of the law.

The principle of equivalence operated to a limited extent in precapitalist socioeconomic formations, where production was primarily in kind and where the merchants' exchange transactions were for the most part nonequivalent. Under the conditions of capitalist commodity production, the equivalence principle reaches full development.

The transformation of labor power into a commodity means that the purchase and sale of labor power are in accordance with the law of value—that is, they are based on the equivalence principle. The capitalist pays for labor power on the basis of value, and hence the equivalence principle retains its significance in the sphere of exchange. The use of labor power, however, entails not only the formation of new value but also an increase in value—that is, the production of surplus value.

The value of labor power and the value created by it are of different magnitudes. On the one hand, the equivalence principle is not violated, and the transaction between capitalists and hired workers is based on the law of value. In the production sphere, on the other hand, the increase in value is automatic, and a greater amount of live labor is exchanged for a lesser amount of embodied labor. Capitalist production is characterized by the exploitation and appropriation of the unpaid labor of hired workers. Consequently under capitalism the equivalence principle contradicts its own content.

In socialist society, the principle of value equivalence loses its general meaning. The dominance of public ownership excludes the exploitation of man by man. Labor power ceases to be a commodity and is joined to the means of production by a directly social method. Relations between society and individual members are regulated by the principle of labor equivalence: "the individual producer receives back from society—after the deductions have been made—exactly what he gives to it" (*ibid.*, vol. 19, p. 18).

The law of distribution according to labor, which underlies the principle of labor equivalence, presupposes that the extent to which all working people share in the total consumption fund is determined by the magnitude of their labor input. Whereas in the case of value equivalence the exchange of equal values is observed only on the average, in the case of labor equivalence the amount of labor that the producer gives to society in a certain form is always returned to him in another form (*ibid*).

Together with the principle of labor equivalence, the principle of value equivalence is also preserved under socialism. The principle of value equivalence occupies a subordinate place in the system of socialist production relations; this is because social production is regulated not by the law of value but by the law of planned proportional development of the national economy. Nonetheless, the existence of commodity-money relations presupposes a value relationship between relatively separate enterprises as well as between the enterprises and society. The profit-and-loss accounting system represents such a value relationship. In profit-and-loss accounting relations, the operation of the equivalence principle does not negate the possiblity of planned deviation of prices from value in the interest of the socialist economy.

A. A. KHANDRUEV [29–1746–6]

EQUIVALENCE, PRINCIPLE OF, the assertion that the gravitational field in a small region of space and time is identical in its manifestation to an accelerated frame of reference. The essence of the equivalence principle is as follows. In a gravitational field all bodies move with the same acceleration, regardless of their mass and other properties (Galileo's law). In the absence of a gravitational field, however, when an observation is made from an accelerated frame of reference, such as a rocket moving with an acceleration imparted by an engine, all bodies undergoing inertial motion also have the same acceleration with respect to the reference frame. In this sense, an accelerated reference frame is equivalent to a gravitational field.

The equivalence principle is called the weak equivalence principle only when applied to the laws of motion of bodies in space. In creating the general theory of relativity (the theory of gravitation), Albert Einstein assumed that not only mechanical motion but all physical processes, given identical initial conditions, proceed identically within and without a gravitational field but in an accelerated reference frame. This assertion is called the strong equivalence principle. The equivalence principle is local; that is, the identity of a gravitational field with an accelerated reference frame is valid only in the small region of space and time in which the gravitational field may be assumed homogeneous and constant in time. The equivalence principle has been proved experimentally to high accuracy (*see* GRAVITATION).

I. D. NOVIKOV [29–1748–1]

EQUIVALENCE RELATION, an equality-type relation, that is, a binary relation that is reflexive, symmetric, and transitive. For example, if two geometric figures are congruent or similar or if two sets of objects are isomorphic or equipotent, the figures or sets are equal or identical in some regard. Thus, isomorphic sets are indistinguishable in structure if by "structure" is meant the aggregate of the properties with respect to which the sets are isomorphic.

[29–1748–2]

EQUIVALENT. The equivalent of an element is the weight, expressed in carbon mass units, that will combine with or replace one atomic weight of hydrogen or one-half atomic weight of oxygen.

The equivalent of an acid is equal to the acid's molecular weight divided by its alkalinity (number of hydrogen ions).

The equivalent of a base is equal to the base's molecular weight divided by its acidity (number of hydroxyl groups).

The equivalent of a salt is equal to the molecular weight of the salt divided by the sum of the charges of the cations or anions forming the salt.

In oxidation-reduction reactions, the equivalent of an oxidizing agent is equal to the quotient obtained as a result of dividing the agent's molecular weight by the number of electrons obtained by the atom or atoms of the reduced element. The equivalent may vary, depending on the number of electrons accepted by the oxidizing agent.

The concept of equivalent is widely used in the stoichiometric calculations of chemical reactions. S. A. POGODIN [29–1746–2]

EQUIVALENT POWER, an arbitrary power rating used, for example, in the analysis of statistical data to compare engines, machines, and other equipment of different powers in order to depict them as a given number of machines having the same power rating. Thus, data on a tractor fleet in the USSR are sometimes converted into arbitrary units of 15-hp tractors (1 hp = 0.736 kilowatt), that is, 15 hp at the drawbar is taken to be the equivalent power. A tractor that develops 75 hp at the drawbar, then, is equivalent to five tractors of 15 hp each. [29–1746–4]

EQUIVALENTS, LAW OF, a law of chemistry according to which the proportions of the masses of substances entering into chemical reaction are equal to or multiples of their equivalent weights. At the end of the 18th century, J. Richter presented a partial formulation of the law for the neutralization of an acid by a base; the law was formulated in more general terms by the British chemist W. Wollaston in 1807. [29–1749–2]

ERIC THE RED (also Eric Thorvaldsson). Tenth-century Norse navigator; father of Leif Ericson.

In 981 or 982, Eric the Red was the first to explore the southern and southwestern coasts of Greenland and gave the island its name. He established the first Norse settlements on its southern coast. In 985, Eric returned to Greenland. [29–1729–3]

ESOCIDAE, a family of fishes of the suborder Esocidei. The body is sagittate and reaches 1.5 m in length and 35 kg in weight. The head is large, and the snout extremely elongated and flattened on top. The teeth are located on the intermaxillary bones, vomer, palatal bones, lower jaw, and tongue. The mandibular teeth are dagger-shaped. The gill membranes are not fused. The operculum is rectangular and elongate. Small scales cover the body and head.

The family contains a single genus, *Esox* (pike), with the two subgenera *Esox* and *Kenoza*, which embrace five extant species. The northern pike (*E. lucius*) is distributed in northern waters of Europe, Asia, and America, and the Amur pike (*E. reicherti*) inhabits the basin of the Amur and bodies of water on Sakhalin Island. The muskellunge (*E. masquinongy*), the common pickerel (*E. niger*), and the redfin pickerel (*E. americanus*) are found only in eastern North America.

The Esocidae inhabit fresh or slightly brackish waters with rich vegetation. They feed on other fishes, including their own young, as well as frogs, small rodents, and swimming birds. They reach sexual maturity in three to four years. The fish spawn in early spring and early summer near the coast in shallows (0.4–1 m). They deposit 17,500–215,000 roe on coastal plants. The eggs adhere to the plants and in two or three days fall to the bottom and develop there. The Esocidae are popular commercial fish. In some places, for example, in the Byelorussian SSR, they are farmed.

The Esocidae are known in fossil form from the Oligocene.

ESOCOIDEI, a suborder of bony fishes of the order Salmoniformes. The soft fin rays have no barbs. The adipose fin is absent, and the dorsal and anal fins are usually located on the rear third of the body. The teeth are located on the premaxillary and palatine bones, on the dentry and vomer, and at the base of the gill and hyoid apparatus. The swim bladder is connected to the intestine. The scales are cycloid. The Esocoidei are predatory fish; some are omnivorous. They are distributed in the temperate zones of the northern hemisphere, usually in freshwaters. Fossils have been found in late Paleocene and in Eocene deposits. The suborder comprises three families: Esocidae, with the single genus *Esox* (pikes); Umbridae (mudminnows); and Dallidae (blackfish).

[29–1618–3]

ESOPHAGITIS, inflammation of the mucosa of the esophagus. Esophagitis may be an independent disease or, more often, a symptom of another disease of the esophagus, stomach, or other organ. The inflammation is frequently caused by chemical, mechanical, or thermal irritation of the esophagus; for example, it may be caused by eating very hot and spicy food.

Catarrhal, phlegmonous, necrotic, and other forms of esophagitis are distinguished based on the severity of the inflammatory changes. In severe cases the inflammatory process may extend to the muscular layer of the esophagus, and sometimes, to the surrounding mediastinal tissue, giving rise to mediastinitis. One form of the disease, peptic esophagitis, is caused mostly by a reflux of the acidic contents of the stomach into the esophageal lumen in cases of hiatus hernia. Peptic esophagitis is sometimes associated with the development of an ulcer in the esophageal wall.

The course of the disease may be acute or chronic. Chronic esophagitis is frequently caused by alcohol abuse or smoking. The symptoms include a burning sensation, retrosternal pain on swallowing, excessive salivation, and regurgitation of food. Esophagoscopy is sometimes used to diagnose the disease. Treatment is by diet (eliminating coarse, hot, and acidic foods), pain relievers, astringent and antispasmodic drugs, and, in some forms, antibiotics and surgery.

I. V. IAREMA [29–1696–1]

ESOPHAGOSCOPY, examination of the inner surface of the esophagus with a special instrument, esophagoscope, which is equipped with an optical system. The esophagoscope is introduced through the mouth under local or general anesthesia. Esophagoscopy is used for diagnostic and therapeutic purposes. It is helpful in detecting tumors and other diseases of the esophagus, as well as the cicatricial narrowing of the esophageal lumen. Esophagoscopy is also used in taking a biopsy, performing bougienage, and locating and removing a foreign body. The once widely used rigid steel esophagoscopes were replaced in the 1970's by flexible and less traumatic fiberscopes. [29–1696–2]

ESOPHAGOTOMY, incision or transection of the esophageal wall to open and pass through the lumen of the esophagus. Esophagotomy is performed to remove foreign bodies from the esophagus or eliminate any obstruction, for example, a tumor. Transection of the esophagus and healing of its ends to the skin are used in experimental physiology (*see* SHAM FEEDING). [29–1695–3]

ESPALIER, a method of crop cultivation by which the above-ground portion of the plant is attached to some type of support, or espalier (poles, stakes, trellises made from rods, walls, or frames with several rows of wire or cord stretched across them). This method of cultivation is used for grapevines, fruit trees, berry shrubs, vegetable crops, and ornamental plants. [29–1386–2]

ESPIONAGE, a crime involving the secret gathering or stealing of information (including economic information) that constitutes state secrets with the intent of turning the information over to another state to the detriment of the state from which the information was taken. Espionage is treated as a crime by the legal systems of all countries. It is one type of subversive activity used by imperialist intelligence services against the USSR and other countries of the socialist camp.

Under Soviet criminal law, espionage is defined as an especially dangerous state crime involving the transmission, or the stealing or gathering with the intent to transmit, of military or state secrets to a foreign state or organization or to agents thereof. It may also include the transmission of other information to be used against the interests of the USSR or the collection of such information on commission from a foreign intelligence agency.

Espionage is considered to have been committed from the moment that the information is obtained, regardless of whether or not it has been transmitted. An unsuccessful attempt to obtain espionage information—for example, an attempt to buy a state secret from a person who legally possesses it—constitutes attempted espionage. If classified state or military information has been obtained and transmitted, the actions of the guilty person are defined as espionage, whether he acted on his own initiative or on commission from a foreign state or organization or from agents thereof. Obtaining and transmitting other information is defined as espionage if these actions are performed on commission from foreign intelligence bodies and if the information is obtained or transmitted for use against the interests of the USSR.

Espionage committed by a citizen of the USSR is treason against the homeland. It carries a sentence of ten to 15 years' deprivation of freedom with confiscation of property, with or without additional exile for a term of two to five years, or execution with confiscation of property (art. 64 of the Criminal Code of the RSFSR and the corresponding articles of the criminal codes of the other Union republics). Espionage committed by a foreigner or person without citizenship is punishable by deprivation of freedom for seven to 15 years with confiscation of property, with or without additional exile for a term of two to five years, or by execution with confiscation of property (art. 65 of the Criminal Code of the RSFSR and the corresponding articles of the criminal codes of the other Union republics).

Espionage is used extensively by the bourgeois states. The USA, for example, has a special intelligence agency known as the Central Intelligence Agency. Intelligence divisions within other departments and ministries also perform espionage and intelligence-gathering activities. At the same time, every capitalist state maintains extremely harsh punishments for espionage committed against it. In accordance with the criminal code of France, espionage is punished by execution. The penalty under British law is execution or hard labor.

Liability for military espionage—that is, secretly and under false pretenses collecting information about the enemy in a zone of military action for the purpose of transmitting the information to one's own command—is regulated by international law under the Statute on the Laws and Customs of Land Warfare, which is appended to the Hague Convention of 1907. A state that has arrested a spy has the right to punish him according to the state's discretion, after a legal trial. [29–1397–2]

EUCALYPTUS, a genus of plants of the family Myrtaceae. The genus consists mainly of evergreen trees frequently reaching a height of 100 m; there are some shrubs. The arrangement and shape of the leaves vary according to the age of the plant. The leaves are always entire, and they are usually fragrant owing to the presence of essential oil. The flowers are regular and bisexual. There are numerous stamens, and the ovary is inferior. The fruit is a capsule consisting of a truncated woody calyx tube to which the ovary is fused.

There are more than 525 species of eucalyptus; they are commonly found in Australia and Tasmania, as well as on neighboring islands. The USSR has more than 30 cultivated species, growing mainly on the Black Sea coast of the Caucasus. Almost all subtropical and tropical countries cultivate eucalypts, since the plants yield valuable wood and grow rapidly. Also of economic value are the leaves, which yield essential oil, and the bark, which yields tannins. Eucalyptus oil and eucalyptus teas or tinctures are used medicinally as antiseptic and anti-inflammatory rinses and inhalants to treat infections of the upper respiratory tract; the medicines are also used to treat wounds and some gynecological disorders. A eucalyptus tincture may also be prescribed to treat inflammation of the mouth and, sometimes, as a sedative.

EUCALYPTUS FORESTS, forests of various species of eucalyptus. Eucalyptus forests are common in Australia and, to a lesser extent, in Tasmania and Indonesia. Because of the vertical arrangement of eucalyptus leaves, a significant amount of light penetrates the forest canopy, and a well-expressed grass stratum and, often, a brush stratum form.

Eucalyptus forests are most widespread in regions having a subtropical climate with atmospheric precipitation occurring in the winter. The height and density of the stand diminish as the climate becomes more arid. In the more humid regions of southwestern Australia, where atmospheric precipitation is more than 1,250 mm a year, there are forests of *Eucalyptus diversicolor*. The open stands have an average canopy height of 60–75 m. In the drier eastern regions, where precipitation totals 625–1,250 mm a year, low eucalyptus forests of *Eucalyptus marginata*, averaging 15–20 m in height, occur. Fully developed brush and grass strata predominate, and insectivorous plants are characteristic. In the center of the continent, where atmospheric precipitation is 500–625 mm, there are open woodlands of *Eucalyptus nedunca* spp. *wando*. In arid regions low eucalyptus savannas, called mollees, occur. [29–1650–4]

EUCALYPTUS OIL, a natural essential oil obtained from the leaves and young shoots of various eucalypts by distilling with steam. The most important eucalyptus oil is obtained from the Tasmanian blue gum (*Eucalyptus globulus* Labill); its primary component is cineole. A colorless or light yellow liquid, it has a cooling taste and a camphoraceous-ethereal odor. The density at 15°C is 0.905–0.922 g/cm^3. The oil is used in medicine.

Another oil is obtained from *Eucalyptus dives*, which contains piperitone, the source of thymol and menthol. The oil derived from *Eucalyptus citric dora* Hook is a component of fragrances for bath soap and a source of citronellal. [29–1650–3]

EUCKEN, RUDOLF. Born Jan. 5, 1846, in Aurich, East Friesland; died Sept. 15, 1926, in Jena. German idealist philosopher.

A follower of J. G. Fichte, Eucken formulated the concept of a "metaphysics of the spirit." He was professor of philosophy in Basel from 1871, and in Jena from 1874.

Eucken opposed the positivist-naturalist world view and called for a revival of idealist metaphysics. Asserting the eternity and unity of the spiritual world and its absolute meaning and value, Eucken worked out a "noological" interpretation of spiritual life whereby the latter was regarded not only as a psychological phenomenon but also as an eternal value. He called for the establishment of a vitalist religious system with a personalized being at its

center, and he considered spiritual life to be permeated with moral principles. Although he viewed religion as the absolute basis of spiritual life, he criticized its historical forms and had a negative attitude toward the church.

Eucken was awarded the Nobel Prize for literature in 1908.

EUCKEN, WALTER. Born Jan. 17, 1891, in Jena; died Mar. 20, 1950, in London. German economist.

Eucken received his doctorate from the University of Berlin in 1921. He became a professor at the University of Tübingen in 1925 and was a professor at the University of Freiburg from 1927 to 1950. Eucken was a theorist of West German neoliberalism, a doctrine of large-scale monopoly capital that advocates government intervention in the economy but disguises it as a defense of free enterprise.

According to Eucken, all economic systems in the history of mankind can be divided into two ideal types: free-market economies and centrally managed economies. In this classification, which is based on forms of economic management, the socialist economy is treated as a centrally managed economy, a category that includes, along with the economic systems of the pharaohs and feudalism, the economy of fascist Germany. The socialist economy is regarded as a "supermonopoly," allegedly lacking effective management, as opposed to a "rational and harmonious social market economy," such as that of the Federal Republic of Germany.

Eucken's theory, which distorts the nature of socialism and socialist planning, is demagogic in character and attempts to conceal the growing strength of large-scale monopoly capital.

EUCLASE, a mineral of the nesosilicate subclass, with the chemical composition $AlBe[SiO_4](OH)$. Euclase contains admixtures of Ge, Mn, Cu, and, sometimes, Y, B, Sn, Zn, and Pb.

Euclase crystallizes in the monoclinic system. Its structure consists of zigzag-like chains of $[BeO_3(OH)]$ incrustated with SiO_4 tetrahedrons. The latter are bound by aluminum atoms in octahedral coordination. Lamellar and short and long prismatic crystals are typical, as well as plumose and divergent aggregates, seldom larger than 1 cm across. Vertical striation is common on the facets of the prism. Euclase may be colorless, milky white, light yellow, pale blue, or greenish. It has a vitreous luster and is transparent to translucent. It typically has perfect cleavage. Its hardness on Mohs' scale is 7.5, and its density is 3,020–3,100 kg/m^3.

Euclase is usually found in hydrothermal deposits of the fluorite-phenakite-bertrandite formation, where it is associated with muscovite, quartz, fluorite, phenakite, and bertrandite or with tourmaline, fluorite, and chrysoberyl. It sometimes occurs in granitic pegmatites, where it develops together with bertrandite after beryl, and in alpine veins. Large transparent crystals of euclase are gems of order, or class, I. Euclase, together with phenakite, bertrandite, and sometimes chrysoberyl, is included in the composition of complex beryl ores.

EUCOMMIA, the sole genus of plants of the family Eucommiaceae. The single species, *Eucommia ulmoides*, is native to China. A deciduous tree reaching 10–20 m in height, it has elongate or oblong-ovate serrated alternate leaves. Some shrub forms are known. The plants are mostly dioecious, with small regular flowers lacking a perianth. The ovary consists of two carpels but is single-valved. The fruit is closed, usually one-seeded, and winged. There are laticiferous cells in all parts of the plant except the wood and seeds; the cells contain gutta, the main component of gutta-percha.

Since early antiquity, *Eucommia* has been used as a medicinal plant to treat broken bones and various internal diseases; it has also been used as a tonic. In the USSR the plant is cultivated primarily in Transcaucasia, Krasnodar Krai, Moldavia, and Middle Asia mainly for the extraction of gutta-percha. It is also cultivated as an ornamental. The bark is used medicinally for the preparation of decoctions, fluid extracts, and tinctures that are used as antispasmodic and hypotensive agents to treat the early stages of hypertension.

M. E. KIRPICHNIKOV [29–1651–4]

EUDAEMONISM, in ancient times the interpretation of life and later, in ethics, the interpretation and theoretical justification of morality according to the principle that happiness, or "bliss," is man's highest goal.

A premise of ancient eudaemonism was the Socratic idea of inner freedom, achievable through the individual's self-knowledge and nondependence on the outside world. Although eudaemonism and hedonism arose at the same time and were closely interrelated, they are in a certain sense opposites. Happiness is not simply Aristotle's protracted and harmonious pleasure but rather the result of overcoming the desire for sensual gratification—a result achieved through practice, self-restraint, asceticism, renunciation of one's attachment to the outside world and its blessings, and consequent freedom from external necessity and from the vicissitudes of life; happiness is judicious reasoning, identical to true virtue.

For the Cynics, the governing principle of life is the struggle against the passions that enslave mankind. The Cyrenaics' doctrine is essentially an elaboration of the same motifs—namely, that happiness depends not on external circumstances but on the right attitude toward them. The Stoics define man's inner freedom as the joyful submission to fate, inasmuch as what has meaning for man depends only on man's attitude toward external circumstances and not on life's vicissitudes.

In the modern age this ideal of inner freedom has been developed by many philosophers; B. Spinoza, in particular, showed exceptional acuity in his antithesis between rational consciousness and sensual passions and in his purely intellectual conception of bliss—*amor dei intellectualis*, or "intellectual love of god."

The French materialists, such as C. A. Helvétius and P. Holbach, gave the concept of happiness a frankly hedonist cast; naturalist motifs became predominant in eudaemonism, as can be seen particularly in English utilitarianism.

T. A. KUZ'MINA [29–1638–1]

EUDES, ÉMILE FRANÇOIS DESIRÉ. Born Sept. 12, 1843, in Roncey; died Aug. 5, 1888, in Paris. Member of the Paris Commune of 1871; Blanquist.

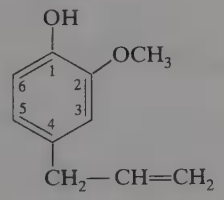
Eudes contributed to Blanquist publications and took an active part in the work of the organization that was founded by L. A. Blanqui in 1868 and 1869. For his participation in the Blanquist uprising that took place on Aug. 14, 1870, in the la Villette quarter of Paris, he was sentenced to death; he was subsequently freed, however, as a result of the September Revolution of 1870. During the seige of Paris by Prussian troops, Eudes was the commander of a battalion of the National Guard. He played a prominent role in the uprising of Mar. 18, 1871. Eudes was a member of the Paris Commune and served on its executive and military commissions. He commanded one of the columns of the National Guard in its march on Versailles on Apr. 3 and 4, 1871.

Eudes emigrated after the fall of the Commune, but he returned to France after the amnesty of 1880 was declared. Eudes was one of the leaders of the Blanquist Central Revolutionary Committee, which was formed in 1881. [29–1677–5]

EUDIALYTE, a mineral; a zirconium silicate with the chemical composition $Na_2Ca_6Fe_3Zr_3[Si_3O_9]_2[Si_9O_{24}(OH)_3]_2$. Eudialyte contains 12–14.5 percent ZrO_2 and admixtures of rare-earth elements (up to 7 percent TR_2O_3). It crystallizes in the trigonal system, forming lamellar, prismatic, and rhombohedral crystals. It usually occurs in the form of granular masses. It is raspberry red, pink, brown, or yellow and has an imperfect cleavage and a vitreous luster. Its hardness on Mohs' scale is 5, and its density is 2,600–3,190 kg/m^3.

Eudialyte fuses easily and dissolves in acids. It is found in nepheline syenites, syenitic pegmatites, albite-aegerine metasomites, and other rocks. It occurs on the Kola Peninsula and in Scandinavia, Tuva, Krasnoiarsk Krai, the Saian Mountains, Canada, and elsewhere. When it occurs in significant accumulations, eudialyte is a source of zirconium. [29–1638–2]

EUGENOL (also 4-allyl-2-methoxyphenol), a yellowish liquid having the structural formula



Eugenol has the odor of cloves. It is soluble in alcohol and ether and slightly soluble in water. It has a melting point of 10.3°C, a boiling point of 252.7°C, and a density of 1.066 g/cm^3 at 20°C. Eugenol is extracted from essential oils, including clove oil, which has a eugenol content of up to 95 percent, and the oil of East Indian basil, which is approximately 70 percent eugenol. It can be synthesized from such compounds as guaiacol.

Eugenol is used as an aromatic substance in the manufacture of perfumes and vanillin. [29–1636–4]

EUGEOSYNCLINE, the inner, more mobile part of a geosynclinal system and the part permeated with products of magmatism, in contrast to the outer, less mobile miogeosynclinal zones that adjoin the platforms. Eugeosynclines are usually extended linear zones, stretching hundreds or thousands of kilometers. The lower parts of their stratigraphic cross sections are usually composed of ophiolites, and the upper parts, of detrital graywacke beds, flysch, and reef limestones, primarily associated with andesitic volcanic rocks. The layers are intricately folded, often forming imbricate structures and overthrust nappes; the latter may be shifted. The development of eugeosynclines ends with the formation of intricately constructed folded zones with a continental crust. High-temperature metamorphism develops parallel with deformation, in the course of which a granite-metamorphic layer gradually forms.

Examples of eugeosynclines are the Tagil'-Magnitogorsk Zone of the Urals and the Piedmont region of the Alps. Typical eugeosynclines first undergo an oceanic stage of development, with the formation of abyssal sediments and basic volcanic rocks. This is followed by the stage of island arcs and marginal seas. Thus, eugeosynclines emerge in place of former ocean basins (or marginal seas with an oceanic crust) and active transitional zones between the ocean and the continent, which were included in the folded belts of the continents during orogenic processes. An important group of minerals is found in eugeosynclines: ores of platinum, chromium, iron, and copper; complex ores and asbestos ores.

L. P. ZONENSHAIN [29–1636–5]

EUGLENA, a genus of microscopic motile single-celled organisms of the division Euglenophyta. The cell is spindle- or ribbon-shaped, with a pellicle in front, a single external flagellum, and a stigma next to the gullet. The ocellus is red. The chloroplasts are green and frequently complex in structure.

About 60 species of euglenas are known. They mainly inhabit shallow bodies of water, where they swim at any depth. Some species, such as *Euglena viridis*, can discard the flagellum and creep or, after taking on a spherical form, live immobile on the surface of the water, silt, or soil. Under unfavorable conditions they become transformed into spores. Nutrition is usually myxotrophic, or if there is a loss of chlorophyll, saprophytic. The organisms are distributed widely and sometimes cause the coloration of waters. *Euglena sanguinea*, which is rich in carotene, makes water red. Euglenas are used in laboratory experiments. [29–1637–1]

EUGLENOPHYTA, a division of microscopic algae usually consisting of a single free-swimming cell. Colonial forms are rare. The nucleus is clearly pronounced, and the green, rarely colorless, chloroplast may lack pyrenoids. The plastmatic cover, or periplast, of some species bears hard, iron-incrusted capsules. At the anterior end of the cell there is a gullet, through which one, two, or sometimes more flagella extend. The contracting vacuoles and stigma are located on the sides of the gullet. In creeping forms the flagellum is rudimentary. Reproduction is by means of longitudinal splitting. Under unfavorable conditions, some species discard their flagella and form protective spores (cysts). Nutrition is primarily phototrophic in green individuals and saprophytic and holozoic (according to the animal type) in colorless individuals. Parasitic species are few in number. The carbohydrate paramylum and oil serve as a food reserve.

There are about 60 genera, embracing more than 900 species, usually found in shallow reservoirs rich in organic matter. The USSR has 33 genera, with 429 species. The algae give water a green, red, or brown coloration when they grow abundantly. Many zoologists classify the Euglenophyta among the Protozoa.

L. A. RUNDINA [29–1637–2]

EULER, LEONHARD. Born Apr. 4 (15), 1707, in Basel, Switzerland; died Sept. 7 (18), 1783, in St. Petersburg. Mathematician, physicist, and mechanics specialist.

Euler received his initial education from his father, Paul Euler, a village pastor of modest means who as a young man had studied mathematics under Jakob Bernoulli. From 1720 to 1724, L. Euler studied at the University of Basel, where he attended the mathematics lectures of Johann Bernoulli.

In late 1726, Euler was offered a position at the St. Petersburg Academy of Sciences, and in May 1727 he arrived in St. Petersburg. The academy, which had just been organized, provided him with favorable conditions for scientific work, and he immediately undertook research in mathematics and mechanics. During the 14 years of the first St. Petersburg period of his life, he prepared approximately 80 works for publication and published more than 50. He learned Russian in this period.

Euler took part in various activities of the academy. He gave courses at the Academy University, was a member of several commissions of technical experts, and worked on the compilation of maps of Russia. In addition to writing the popular *Einleitung*

in die Arithmetik (Introduction to Arithmetic; 1738–40; Russian translation, parts 1–2, 1740), he prepared, at the academy's request, *Scientia navalis* (Naval Science; parts 1–2, 1749), a basic work on the theory of shipbuilding and navigation.

In 1741, Euler accepted an invitation from Frederick II, the king of Prussia, to join the Berlin Academy of Sciences, which Frederick was planning to form from the academy founded by G. W. von Leibniz. In Berlin, Euler was appointed director of the academy's mathematics class and a member of the board. He ran the academy for several years after the death of its first president, P. L. de Maupertuis. In his 25 years in Berlin, Euler produced approximately 300 works, including several large monographs.

While living in Berlin, Euler continued to work intensively for the St. Petersburg Academy of Sciences, of which he remained an honorary member. He carried on an extensive correspondence dealing with scientific and organizational matters; in particular, he corresponded with M. V. Lomonosov, whom he highly esteemed. Euler edited the mathematics section of the Russian academy's journal, in which he published during this period nearly as many papers as in the *Mémoires* of the Berlin Academy of Sciences. He helped train Russian mathematicians; the future academicians S. K. Kotel'nikov, S. Ia. Rumovskii, and M. Sofronov were sent to Berlin to study under his direction. Euler greatly assisted the St. Petersburg Academy of Sciences by, for example, acquiring scientific literature and equipment and negotiating with candidates for positions at the academy.

On July 17 (28), 1766, Euler and his family returned to St. Petersburg. Despite his age and the nearly total blindness that befell him, he worked productively to the end of his life. In the 17 years of his second stay in St. Petersburg he wrote approximately 400 works, including a number of large books. Euler continued to be involved in organizational work at the academy. In 1776 he was a member of the commission of experts appointed to study I. P. Kulibin's design for a single-arch bridge across the Neva River; Euler was the only one on the commission to offer enthusiastic support for the project.

Euler's accomplishments as a scientist and organizer of scientific research won wide recognition during his lifetime. In addition to the St. Petersburg and Berlin academies, he was a member of such prominent scientific institutions as the Académie des Sciences in Paris and the Royal Society of London.

Euler was extraordinarily prolific. Approximately 550 of his books and papers were published during his lifetime. He produced a total of approximately 850 works. In 1909 the Swiss Society of Natural Sciences undertook the publication of his complete collected works. The edition, which was completed in 1975, consists of 72 volumes. Euler's immense scientific correspondence, which comprises approximately 3,000 letters, is also of considerable value; it has been published only in part.

The range of Euler's interests was unusually broad. In addition to all branches of the mathematics of his time, it included mechanics, elasticity theory, mathematical physics, optics, music theory, the theory of mechanisms, ballistics, naval science, and insurance. Approximately three-fifths of Euler's works pertain to mathematics, and the remaining two-fifths pertain chiefly to applications of mathematics.

Euler systematized his own findings and those of others in several classic monographs, which were written with remarkable clarity and provided with valuable examples. These monographs include *Mechanica, sive motus scientia analytice exposita* (Mechanics, or the Science of Motion Expounded Analytically; vols. 1–2, 1736); *Introductio in analysin infinitorum* (Introduction to the Analysis of Infinitesimals; vols. 1–2, 1748); *Institutiones calculi differentialis* (Principles of Differential Calculus; 1755); *Theoria motus corporum solidorum seu rigidorum* (Theory of the Motion of Solid or Rigid Bodies; 1765); *Vollständige Anleitung zur Algebra* (Complete Introduction to Algebra; first published in Russian translation, vols. 1–2, 1768–69), which was published in about 30 editions in six languages; and *Institutiones calculi integralis* (Principles of Integral Calculus; vols. 1–3, 1768–70; vol. 4, 1794). Euler's *Lettres à une princesse d'Allemagne sur quelques sujets de physique et de philosophie* (Letters to a German Princess on Various Matters of Physics and Philosophy; parts 1–3, 1768–74) was published in more than 40 editions in ten languages. Lucidly written, it enjoyed great popularity in the 18th century and was still read in the 19th century. Much of the material in Euler's monographs was subsequently incorporated into textbooks and study guides for higher educational institutions and, to some extent, for secondary schools.

It would be impossible to list all of Euler's theorems, methods and formulas, only a few of which are known in the literature by his name. Among the various mathematical entities or expressions named for him are Euler's constant, the Euler phi-function, Euler numbers, the Euler characteristic, Euler's integrals, and Euler angles.

In *Mechanica* mathematical analysis is applied for the first time to the dynamics of a point. The first volume of the work deals with the free motion of a point under the action of various forces, both in a vacuum and in a medium that offers resistance. The second volume treats of the motion of a point along a given curve or surface. The chapter on the motion of a point under the action of a central force was of great importance in the development of celestial mechanics. In 1744, Euler gave the first correct formulation of the principle of least action and provided the first examples of the principle's application. In *Theoria motus corporum solidorum seu rigidorum* he discussed the kinematics and dynamics of rigid bodies and gave the equations of their rotation about a fixed point, thereby laying the foundations of the theory of gyroscopes. Euler's theory of ships made a valuable contribution to the theory of stability. Among his important discoveries in celestial mechanics are his contributions to the theory of lunar motion. In continuum mechanics he derived the fundamental equations of the motion of an ideal fluid in Eulerian and Lagrangian variables and studied the oscillations of a gas in tubes.

In optics Euler gave in 1747 an equation for a biconvex lens and proposed a method of calculating the refractive index of a medium. An adherent of the wave theory of light, he believed that to different colors there correspond different wavelengths of light. He suggested techniques of eliminating chromatic aberration in lenses and, in the third part of *Dioptrica* (Dioptrics), gave methods of designing the optical assemblies of microscopes.

In a large series of works begun in 1748, Euler studied such problems as the vibration of strings, plates, and membranes. In general his works dealing with physics and mechanics stimulated the development of such fields as the theory of differential equations, approximate methods of analysis, special functions, and differential geometry. They contain many of his mathematical discoveries.

Euler's most important achievements as a mathematician were in the field of mathematical analysis. He laid the foundations of several areas of study that existed only in incipient form or were altogether absent in the infinitesimal calculus of I. Newton, Leibniz, Jakob Bernoulli, and Johann Bernoulli. For example, Euler was the first to introduce functions of a complex variable (*Introductio in analysin*, vol. 1) and to investigate the main elementary functions—that is, exponential, logarithmic, and trigonometric functions—of a complex variable. Of particular value was his derivation of formulas expressing relations between trigonometric functions and exponential functions. Euler's work in this area gave rise to the theory of functions of a complex variable.

Euler was the inventor of the calculus of variations, which he expounded in *Methodus inveniendi lineas curvas, maximi minimive proprietate gaudentes* (A Method of Finding Curves That Enjoy Some Maximum or Minimum Property; 1744). After the appearance of works on the subject by J. Lagrange, Euler further developed the calculus of variations in *Institutiones calculi integralis* and several papers. The method by which he derived in 1744 the necessary condition for the extremum of a functional (Euler's equation) was a prototype of the direct methods developed for the calculus of variations in the 20th century.

Euler created the theory of ordinary differential equations as an independent discipline and laid the foundations of the theory of partial differential equations. Here he made a tremendous number of discoveries. In addition to providing the classical method of solving linear equations with constant coefficients and the method of variation of arbitrary constants, he elucidated the main properties of the Riccati equation, developed the use of infinite series in integrating linear equations with variable coeffi-

cients, and established criteria for singular solutions. He also introduced the concept of an integrating factor, various approximate methods, and a number of procedures for solving partial differential equations. Many of his results are contained in *Institutiones calculi integralis*.

The differential and integral calculus in the narrow sense of the word were also enriched by Euler. In addition to the use of change of variables, his contributions include the proof of an important theorem on homogeneous functions, the introduction of the concept of the double integral, and the calculation of many special integrals. In *Institutiones calculi differentialis* he argued for the use of divergent infinite series and supplied his discussion with examples; he proposed generalized summation methods for series, thereby anticipating the ideas of the modern rigorous theory of divergent series developed at the turn of the 20th century. Moreover, Euler obtained a host of specific results in the theory of series. He discovered the Euler-Maclaurin summation formula, set forth the transformation of series that bears his name, determined the sums of an enormous number of series, and introduced into mathematics important new types of series, such as trigonometric series. His studies in the theory of continued fractions and other infinite processes may also be mentioned in this connection.

Euler was the founder of the theory of special functions. He was the first to treat the sine and cosine as functions rather than as line segments in a circle. He derived nearly all the classical expansions of elementary functions in infinite series and products. He originated the theory of the gamma function and investigated the properties of elliptic integrals, hyperbolic and cylindrical functions, the zeta function, some theta functions, the logarithmic integral, and important classes of special polynomials.

As P. L. Chebyshev notes, Euler was a pioneer in all the principal areas of the theory of numbers, to which more than 100 of his papers pertain. For example, he proved several assertions made by P. de Fermat (for example, Fermat's lesser theorem), developed the foundations of the theory of power residues and the theory of quadratic forms, discovered (but did not prove) the law of quadratic reciprocity (*see* QUADRATIC RESIDUE), and investigated a number of problems of Diophantine analysis. In his works on the expression of numbers as sums of other numbers and on the theory of primes, Euler was the first to use methods of analysis, thus becoming the founder of the analytic theory of numbers. In particular, he introduced the zeta function and proved a formula giving a relation between prime numbers and natural numbers [*see* EULER FORMULA: (3)].

Euler's contributions also were great in other areas of mathematics. In algebra he wrote papers on the solution by radicals of higher-degree equations, on equations in two variables, and on the sum of four squares [*see* EULER FORMULA: (4)]. Euler substantially advanced analytic geometry, especiallly with respect to quadric surfaces. In differential geometry he investigated in detail the properties of geodesics. He was the first to use natural equations of curves. His most important contribution in this area was that he laid the foundations of the theory of surfaces. He introduced the concept of principal directions at a point on a surface, proved the orthogonality of the principal directions, derived a formula for the curvature of any normal section, and initiated the study of developable surfaces. In a work published posthumously in 1862, he partially anticipated the studies of K. F. Gauss on the intrinsic geometry of surfaces. Euler also worked on some problems of topology and proved, for example, an important theorem on convex polyhedra.

As a mathematician Euler is often described as a brilliant calculator. He was in fact an unsurpassed master of formal computations and transformations. In his works many mathematical formulas and symbols took on their modern form; for example, he introduced the symbols e and π. Euler, however, was not just a calculator of exceptional power. He set forth a number of profound ideas that since his day have been given rigorous substantiation and that serve as models of deep insight into the objects of scientific inquiry.

P. S. de Laplace called Euler the teacher of the mathematicians of the second half of the 18th century. Euler's works provided starting points for investigations in various areas of mathematics by Laplace, Lagrange, G. Monge, A. M. Legendre, and Gauss and later by such mathematicians as A. Cauchy, M. V. Ostrogradskii, and P. L. Chebyshev. Russian mathematicians held his work in high regard. The members of the Chebyshev school viewed Euler as their intellectual predecessor because of his constant sense of the concrete and specific, his interest in concrete difficult problems requiring the development of new methods, and his desire to obtain the solutions of problems in the form of complete algorithms that would make it possible to find the answer to any required degree of accuracy.

EULER, ULF SVANTE VON. Born Feb. 7, 1905, in Stockholm. Swedish physiologist. Son of H. von Euler-Chelpin.

In 1929, von Euler graduated from the Karolinska Institute in Stockholm, where he served as an assistant professor in the pharmacology department in 1930 and became professor of physiology in 1939. In 1930 he worked in H. Dale's laboratory in London, where he discovered the presence of a biologically active polypeptide, substance P, in intestinal tissue. His main research is concerned with the physiology of adrenergic nerve endings. Von Euler discovered that norepinephrine is a neurotransmitter of the sympathetic nervous system. He investigated in detail its distribution in nerves and organs and its metabolism under a variety of physiological and pathological conditions. Von Euler also discovered and studied the function of prostaglandin (1936) and norepinephrine (1946). He found subcellular particles containing norepinephrine and elucidated the mechanisms by which they obtain, store, and release norepinephrine.

Von Euler is a member of the Royal Swedish Academy of Sciences, the Danish Academy of Sciences, the Leopoldina German Academy of Naturalists, and the Royal Society of London (1973). He won a Nobel Prize in 1970, together with B. Katz and J. Axelrod.

EULER ANGLES (or Eulerian angles), the angles ϕ, θ, and ψ that define the position of a rectangular Cartesian coordinate system $OXYZ$ with respect to another rectangular Cartesian coordinate system $Oxyz$ of the same orientation (see Figure 1).

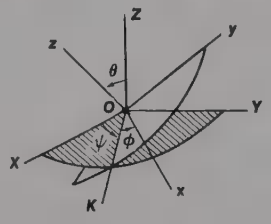

Figure 1

Let OK be an axis, called the line of nodes, that coincides with the line of intersection of the coordinate plane Oxy of the first system with the coordinate plane OXY of the second system and is directed so that the axes Oz, OZ, and OK form a trihedral of the same orientation. The Euler angle ϕ, or angle of spin, is the angle between the axes Ox and OK, which is measured in the plane Oxy from Ox in the direction of the shortest rotation from Ox to Oy. The Euler angle θ, or angle of nutation, is the angle between Oz and OZ; it does not exceed π. The Euler angle ψ, or angle of precession, is the angle between the axes OK and OX, which is measured in the plane OXY from OK in the direction of the shortest rotation from OX to OY. When $\theta = 0$ or π, the Euler angles are not defined.

The Euler angles were introduced by L. Euler in 1748 and are used extensively in the dynamics of solids—for example, in the theory of the gyroscope—and in celestial mechanics. [29–1718–1]

EULER CHARACTERISTIC. The Euler characteristic of a polyhedron is the number $\alpha_0 - \alpha_1 + \alpha_2$, where α_0 is the number of vertices, α_1 is the number of edges, and α_2 is the number of faces. According to Euler's theorem, if the polyhedron is convex or is homeomorphic to a convex polyhedron, then its Euler characteristic is 2. This fact was known to R. Descartes; L. Euler published a proof of the theorem in 1758.

The Euler characteristic of an arbitrary simplicial complex is the number

$$\sum_{k=0}^{n} (-1)^k \alpha_k$$

where n is the dimension of the complex, α_0 is the number of vertices, and α_1 is the number of edges. In general, k is the number of k-dimensional simplexes belonging to the complex. According to the Euler-Poincaré formula, the Euler characteristic is equal to

$$\sum_{k=0}^{n} (-1)^k \pi_k$$

where π_k is the k-dimensional Betti number of the complex. The topological invariance of the Euler characteristic follows from this fact.

In view of the topological invariance of the Euler characteristic, we speak of the Euler characteristic of a surface and of a polytope, by which we mean the Euler characteristic of any triangulation of the surface or polytope.

EULER-CHELPIN, HANS KARL AUGUST SIMON VON. Born Feb. 15, 1873, in Augsburg, Germany; died Nov. 6, 1964, in Stockholm. Swedish biochemist. Member of the Royal Swedish Academy of Sciences. Descendant of L. Euler and father of U. Euler.

Euler-Chelpin graduated from the Munich Academy of Arts in 1893 and then studied chemistry and medicine at the universities of Berlin, Strasbourg, and Göttingen. He organized the Swedish Chemical Society and served as its president from 1908 to 1963. He was a professor at the University of Stockholm from 1906 to 1929. Beginning in 1929, he was director of the Institute of Organic Chemistry and the Institute of Vitamins.

Euler-Chelpin's works were devoted mainly to the mechanisms of various biochemical processes. Euler-Chelpin investigated the kinetics and fermentation mechanism of sugars. He observed that the rate of chemical reactions in living organisms is accelerated by enzymes and suggested calling the phenomenon biocatalysis. He also studied the structure and mechanism of action of vitamin A (with P. Karrer) and demonstrated that β-carotene is provitamin A and is present in eye pigment. He made substantial contributions to the biochemistry of tumors.

Euler-Chelpin received a Nobel Prize in 1929, with A. Harden. He was a foreign member of the Academy of Sciences of the USSR (1927).

EULER-FOURIER FORMULAS, formulas for calculating the coefficients of the expansion of a function in a trigonometric series (Fourier series). The Euler-Fourier formulas are named after L. Euler, who provided their first derivation in 1777, and J. Fourier, who, beginning in 1811, systematically used trigonometric series in the study of problems of heat conduction. (*See* FOURIER COEFFICIENT and TRIGONOMETRIC SERIES.) [29–1717–1]

EULER-MACLAURIN SUMMATION FORMULA, a formula relating the partial sums of an infinite series to the integral and derivatives of the general term of the series:

$$\sum_{k=p}^{m-1} \phi(k) = \int_p^m \phi(t)\,dt + \sum_{\nu=1}^{n-1} \frac{B_\nu}{\nu!} \{\phi^{(\nu-1)}(m) - \phi^{(\nu-1)}(p)\} + R_n$$

where the B_ν are Bernoulli numbers and R_n is the remainder.

The formula is used for the approximate computation of definite integrals, for the investigation of the convergence of infinite series, for the computation of sums, and for the expansion of functions in Taylor's series. For example, if $m = 1$, $p = 0$, $n = 2m + 1$, and $\phi(x) = \cos(xt/2)$, the formula gives the following expression:

$$\frac{t}{2}\cot\frac{t}{2} = \sum_{\nu=0}^{m} (-1)^\nu \frac{t^{2\nu}}{(2\nu)!} B_2 + \frac{(-1)^{m+1} t^{2m+2}}{2\sin(t/2)} \int_0^1 \frac{B_{2m+1}(t)}{(2m+1)!} \sin\left(x - \frac{1}{2}\right)t\,dx$$

First introduced by L. Euler in 1738, the formula was discovered independently by C. Maclaurin in 1742. [29–1716–3]

EULER NUMBER, a similarity criterion used in the study of the motion of liquids or gases.

The Euler number Eu characterizes the relation between the pressure forces acting on an elementary volume of a liquid or gas and the inertia forces. It is defined by the formula

$$Eu = \frac{2(p_2 - p_1)}{\rho v^2}$$

(sometimes $2p/\rho v^2$), where p_2 and p_1 are the pressures at two characteristic points of the flow (or of a body moving in it), $\rho v^2/2$ is the velocity head, ρ is the density of the liquid or gas, and v is the fluid velocity (or the velocity of the body).

In the case of liquid flows with cavitation, the analogous criterion is called the cavitation number $\kappa = 2(p_0 - p_s)/\rho v^2$, where p_0 is the characteristic pressure and p_s is the saturation vapor pressure of the liquid.

For compressible gas flows the relation between the Euler number in the form $Eu = 2p/\rho v^2$ and two other similarity

criteria—the Mach number M and the ratio of the specific heats of the medium γ—is given by the equation $Eu = 2/\gamma M^2$, where $\gamma = c_p/c_v$ (c_p is the specific heat at constant pressure, and c_v is the specific heat at constant volume).

It should be noted that in the American literature two Euler numbers are often used. Euler number 1 equals the friction head divided by two times the velocity head, and Euler number 2 is equal to two times the Fanning friction factor.

The Euler number is named for L. Euler. [29–1716–2]

EULER NUMBERS, in mathematics, the integers E_n that are the coefficients of $t^n/n!$ in the expansion of the function $1/\cosh t$ in the power series

$$\frac{1}{\cosh t} = \sum_{n=0}^{\infty} E_n \frac{t^n}{n!}$$

These numbers, which were introduced by L. Euler in 1755, are related by the formula $(E + 1)^n + (E - 1)^n = 0$, $n = 1, 2, 3, \ldots$, $E_0 = 1$ (after raising to the power, E_k must be inserted for E^k). The following relations hold between Euler numbers and Bernoulli numbers:

$$E_{n-1} = \frac{(4B-1)^n - (4B-3)^n}{2n}$$

$$B_n = \frac{n(E+1)^{n-1}}{2^n(2^n-1)}$$

$$\left(B - \frac{1}{4}\right)^{2n+1} = \frac{2n+1}{4^{2n+1}} E_{2n}$$

Euler numbers are encountered in various formulas of mathematical analysis. [29–1716–1]

EULER PHI-FUNCTION. The Euler phi-function of the natural number a is the number $\phi(a)$ of natural numbers smaller than a and relatively prime to a:

$$\phi(a) = a\left(1 - \frac{1}{p_1}\right) \ldots \left(1 - \frac{1}{p_k}\right)$$

where $p_1, \ldots, p_k$ are the prime factors of a. The function was introduced by L. Euler in 1760 and 1761. If the numbers a and b are relatively prime, then $\phi(ab) = \phi(a)\phi(b)$. Euler's theorem states that if $m > 1$ and the greatest common divisor of a and m is 1 (that is, a and m are relatively prime), then the congruence $a^{\phi(m)} \equiv 1 \pmod{m}$ holds. Euler's phi-function is encountered in many problems of number theory. [29–1715–2]

EULER'S CONSTANT (or Mascheroni's constant), the limit

$$\lim_{n\to\infty} \left\{ \sum_{k=1}^{n} \frac{1}{k} - \ln n \right\} = C = 0.577215 \ldots$$

which was considered by L. Euler in 1740. Euler gave a number of representations for C in the form of series and integrals; for example,

$$C = \int_0^1 \left(\frac{1}{1-x} + \frac{1}{\ln x} \right) dx$$

$$1 - C = \sum_{n=2}^{\infty} \frac{1}{n} \{\zeta(n) - 1\}$$

where $\zeta(s)$ is the zeta function. Euler's constant is encountered in the theory of various classes of special functions, such as the gamma function. It remains unknown whether Euler's constant is an irrational number. [29–1713–4]

EULER'S EQUATION. (1) A differential equation of the form

$$(*) \qquad \sum_{k=0}^{n} a_k x^k y^{(k)} = f(x)$$

where $a_0, \ldots, a_n$ are constants. When $x > 0$, equation $(*)$ reduces, by the substitution $x = e^t$, to a linear differential equation with constant coefficients. Equation $(*)$ was studied by L. Euler in 1740. The equation

$$\sum_{k=0}^{n} A_k (ax + b)^k y^{(k)} = f(x)$$

reduces to it through the substitution $x' = ax + b$.

(2) A differential equation of the form

$$\frac{dx}{\sqrt{X}} + \frac{dy}{\sqrt{Y}} = 0$$

where $X(x) = a_0x^4 + a_1x^3 + a_2x^2 + a_3x + a_4$ and $Y(y) = a_0y^4 + a_1y^3 + a_2y^2 + a_3y + a_4$. Euler considered this equation in a number of works, the first of which dates from 1753. He showed that the general solution of the equation is a symmetric polynomial of degree 4 in x and y. This result provided the basis for the theory of elliptic integrals.

(3) A differential equation of the form

$$\frac{\partial F}{\partial y} - \frac{d}{dx}\left(\frac{\partial F}{\partial y'}\right) = 0$$

which is used in the calculus of variations to search for extrema of the integral

$$\int_a^b F(x, y, y')\, dx$$

The equation was derived by L. Euler in 1744. [29–1714–1]

EULER'S EQUATIONS. (1) In mechanics, dynamical and kinematical equations used in the study of the motion of a rigid body. The equations were introduced by L. Euler in 1765.

Euler's dynamical equations are differential equations of the motion of a body about a fixed point. They have the form

$$(1) \qquad \begin{aligned} I_x\dot{\omega}_x + (I_z - I_y)\,\omega_y\omega_z &= M_x \\ I_y\dot{\omega}_y + (I_x - I_z)\,\omega_z\omega_x &= M_y \\ I_z\dot{\omega}_z + (I_y - I_x)\,\omega_x\omega_y &= M_z \end{aligned}$$

where I_x, I_y, and I_z are the moments of inertia of the body about the principal axes of inertia (the origin of the frame of axes is the fixed point); ω_x, ω_y, and ω_z are the components of the instantaneous angular velocity of the body about the principal axes; M_x, M_y, and M_z are the corresponding moments of the forces acting on the body; and $\dot{\omega}_x$, $\dot{\omega}_y$, and $\dot{\omega}_z$ are the components of the angular acceleration.

Euler's kinematical equations give expressions for ω_x, ω_y, and ω_z in terms of the Euler angles ϕ, ψ, and θ. They have the form

$$(2) \qquad \begin{aligned} \omega_x &= \dot{\psi}\sin\theta\sin\phi + \dot{\theta}\cos\phi \\ \omega_y &= \dot{\psi}\sin\theta\cos\phi - \dot{\theta}\sin\phi \\ \omega_z &= \dot{\phi} + \dot{\psi}\cos\theta \end{aligned}$$

The system of equations (1) and (2) makes it possible to determine the moment of the forces acting on a body if the law governing the body's motion is known. Conversely, the system permits determination of the law governing the motion if the forces acting on the body are known.

(2) In hydromechanics, the differential equations of motion of an ideal fluid in Eulerian variables. Let the pressure p, the density ρ, the components of the fluid-particle velocities u, v, and w, and the components of the body force X, Y, and Z be regarded as functions of the three space coordinates x, y, and z and of time t (Eulerian variables). Then Euler's equations in rectangular Cartesian coordinates are

$$\begin{aligned} \frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} + w\frac{\partial u}{\partial z} &= X - \frac{1}{\rho}\frac{\partial p}{\partial x} \\ \frac{\partial v}{\partial t} + u\frac{\partial v}{\partial x} + v\frac{\partial v}{\partial y} + w\frac{\partial v}{\partial z} &= Y - \frac{1}{\rho}\frac{\partial p}{\partial y} \\ \frac{\partial w}{\partial t} + u\frac{\partial w}{\partial x} + v\frac{\partial w}{\partial y} + w\frac{\partial w}{\partial z} &= Z - \frac{1}{\rho}\frac{\partial p}{\partial z} \end{aligned}$$

The solution of the general problem of hydromechanics in Eulerian variables reduces to determining u, v, w, p, and ρ as functions of x, y, z, and t if X, Y, and Z and the initial and boundary conditions are known. For this purpose, the equation of continuity in Eulerian variables

$$\frac{\partial \rho}{\partial t} + \frac{\partial(\rho u)}{\partial x} + \frac{\partial(\rho v)}{\partial x} + \frac{\partial(\rho w)}{\partial z} = 0$$

is appended to Euler's equations.

In the case of a barotropic fluid, whose density depends solely on pressure, the fifth equation is the equation of state $\rho = \phi(p)$; p is constant if the fluid is incompressible.

Euler's equations are used in solving various problems of hydromechanics.

EULER'S FORMULA, any of several important formulas established by L. Euler.

(1) A formula giving the relation between the exponential function and trigonometric functions (1743):

$$e^{ix} = \cos x + i \sin x$$

Also known as Euler's formulas are the equations

$$\cos x = \frac{e^{ix} + e^{-ix}}{2}$$

$$\sin x = \frac{e^{ix} - e^{-ix}}{2i}$$

(2) A formula giving the expansion of the function $\sin x$ in an infinite product (1740):

$$\frac{\sin x}{x} = \prod_{n=1}^{\infty} \left(1 - \frac{x^2}{n^2\pi^2}\right)$$

(3) The formula

$$\sum_{n=1}^{\infty} \frac{1}{n^s} = \prod_{p} \frac{1}{1 - p^{-s}}$$

where $s = 1, 2, \ldots$ and p runs over all prime numbers.

(4) The formula

$$(a^2 + b^2 + c^2 + d^2)(p^2 + q^2 + r^2 + s^2) = x^2 + y^2 + z^2 + t^2$$

where

$$x = ap + bq + cr + ds$$

$$y = aq - bp \pm cs \mp dr$$

$$z = ar \mp bs - cp \pm dq$$

$$t = as \pm br \mp cq - dp$$

(5) The formula (1760)

$$\frac{1}{R} = \frac{\cos^2 \phi}{R_1} + \frac{\sin^2 \phi}{R_2}$$

Also known as the equation of Euler, it gives an expression for the curvature $1/R$ of a normal section of a surface in terms of the surface's principal curvatures $1/R_1$ and $1/R_2$ and the angle ϕ between one of the principal directions and the given direction.

Other well-known formulas associated with Euler include the Euler-Maclaurin summation formula and the Euler-Fourier formulas for the coefficients of expansions of functions in trigonometric series. [29–1715–1]

EULER'S INTEGRAL. The integral

$$(1) \qquad \mathrm{B}(a, b) = \int_0^1 x^{a-1}(1 - x)^{b-1}\, dx$$

is known as Euler's integral of the first kind or the beta function. It was studied by L. Euler in 1730 and 1731 and had been previously considered by I. Newton and J. Wallis.

The integral

$$(2) \qquad \Gamma(a) = \int_0^{\infty} x^{a-1} e^{-x}\, dx$$

is known as Euler's integral of the second kind or the gamma function. It was considered by Euler in 1729 and 1730 in a form equivalent to equation (2); equation (2) itself was given by Euler in 1781.

The name "Euler's integral" was introduced by A. Legendre. Such integrals make it possible to generalize to the case of continuously varying arguments the binomial coefficients C_m^n and the factorial $n!$: if a and b are natural numbers, then

$$\mathrm{B}(a, b) = \frac{1}{bC_{a+b-1}^{a-1}} \qquad \Gamma(a + 1) = a!$$

Integrals (1) and (2) converge absolutely if a and b are positive; they do not exist if a and b are negative. The following relations hold:

$$\mathrm{B}(a, b) = \mathrm{B}(b, a) \qquad \mathrm{B}(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a + b)}$$

The second relation expresses the beta function in terms of the gamma function. There are a number of relations between Euler's integrals, for different values of the argument, that generalize the corresponding relations between the binomial coefficients. Euler's integrals also may be considered for complex values of the arguments a and b. Euler's integrals are encountered in many problems of the theory of special functions; many definite integrals that do not have an elementary expression reduce to Euler's integrals.

The name "Euler's integral" is also sometimes applied to the integral

$$\int_0^1 u^{b-1}(1 - u)^{c-b-1}(1 - ux)^{-a}\, du = \frac{\Gamma(b)\Gamma(c - b)}{\Gamma(c)} F(a, b, c, x)$$

which expresses the hypergeometric function.

EULER SUBSTITUTIONS, substitutions used to reduce integrals of the form

$$\int R(x, y)\, dx$$

to integrals of rational functions, where $y = \sqrt{ax^2 + bx + c}$ and $R(x, y)$ is a rational function of x and y. The substitutions were proposed by L. Euler in 1768.

The first Euler substitution is

$$\sqrt{ax^2 + bx + c} = t - x\sqrt{a}$$

and is applicable if $a > 0$. The second Euler substitution is

$$\sqrt{ax^2 + bx + c} = xt + \sqrt{c}$$

and is applicable if $c > 0$. The third Euler substitution is

$$\sqrt{ax^2 + bx + c} = t(x - \lambda)$$

where λ is one of the roots of the trinomial $ax^2 + bx + c$; this substitution is applicable if the roots of the trinomial are real. In practice, Euler substitutions require cumbersome transformations, and various artificial procedures that simplify calculation are normally used instead of them.

Similar substitutions are made in number theory in the solution of indeterminate equations of second degree in rational numbers.

[29–1713–3]

EUPHAUSIACEA, an order of higher crustaceans. The body varies in length from 5 to 96 mm. Externally the animals resemble shrimp of the order Decapoda, differing from them in having gills that are not covered by a thoracic shield and that are located on the bases of the thoracic extremities. The biramous thoracic extremities are used only for swimming. The eyes are stalk-shaped; there are photophores on the eye stalks, as well as on the bases of several pairs of thoracic limbs and on the first four abdominal segments. The Euphausiacea are dioecious. Eggs are laid in the water. The larva leaves the egg during the nauplius stage, after which several more developmental stages follow; the cycle from egg to adult is completed in three or four months.

The order embraces approximately 90 known species, which are widely distributed in the world ocean, especially in subtropical and tropical regions. The animals reproduce in large numbers in some seas, where they are the source of food for various marine mammals and fishes. In the waters of Antarctica the accumulation of some species of whale is related to the mass reproduction of krill, including one member of the Euphausiacea, *Euphasia superba*. In the Barents Sea, the mass-reproducing species *Thysanoessa raschii* is a food source for herring, Eurasian perch, Atlantic cod, and other commercial fishes.

EUPHEMISM, the replacement of coarse or offensive words and expressions with less offensive ones or of certain names with conventional designations. Euphemisms are the result of lexical taboos imposed by various prejudices, superstitions, and religious beliefs on the use of the names for specific objects and phenomena in life, thus necessitating other means of expression.

In the early stages of social development of many Indo-European peoples, the names of various animals were euphemisms. Thus, the Russian word *medved'* ("bear") is an artificially created compound meaning "honey-eater"; it replaced an earlier word, which was placed under taboo because of mythological beliefs. Among professional hunters the word *medved'* subsequently underwent a second taboo and was replaced with new euphemisms, such as *khoziain* ("master"), *mokhnach* ("hairy one"), and *lomaka* ("bone breaker"). When taboos are rooted in superstition and prejudice, euphemisms arise for the words for death and illnesses. Thus, Russian *umer* ("he died") is replaced with *otpravilsia k praotsam* ("he went to join his forefathers"), *otdal bogu dushu* ("he gave his soul to god"), or *prikazal dolgo zhit'* ("he ordered a long life").

In a civilized society one of the principal causes for the use of euphemisms is etiquette, which bans the use of coarse or indecent expressions. Thus, instead of saying "you are lying," one says "you are inventing things," "you are mistaken," or "you are not entirely correct." Physicians often use Latin names for illnesses or special medical terms: in Russian, "cancer" and "tbc" (both spelled with Latin letters) may be used for the standard Russian terms *rak* and *tuberkulez; smert'* ("death") may be replaced by *letal'nyi iskhod* ("fatal outcome"). In modern societies, euphemisms are also used to impose censorship on the revelation of military and state secrets. In such cases the proper names of countries, cities, and military units are replaced by letters and conventional designations, such as "N" and "Nth," or by descriptive expressions, such as "a neighboring power."

Some jargons, in addition to embellishments and euphemisms, also use reverse euphemisms, or dysphemisms, which involve the replacement of neutral expressions with coarser, more familiar, or more vulgar ones. Thus, Russian *dat' duba* (literally, "to give the oak"), *sygrat' v iashchik* (literally, "to play the box"), and *skopytit'sia* (literally, "to be knocked off one's feet") may be used for the neutral *umeret'* ("to die"). Such substitutions sometimes serve the purpose of disguising the meaning of conversations likely to be overheard.

EUPHONY, the organization of sound in artistic speech (primarily verse) based on the repetition of sounds; a synonym of phonics. In a narrower sense, the term "euphony" sometimes refers to articulatory and acoustic harmony in speech. A disharmonious succession of vowels at the boundary of two words is called a hiatus. [29–1669–1]

EUPHORIA, an elevated, joyful mood and feeling of satisfaction and well-being not consistent with objective circumstances. Individuals experiencing euphoria are usually optimistic and impervious to negative affects. Euphoria may be combined with an accelerated flow of thoughts and a tendency to vivid fantasizing, energetic but unproductive activity, and disinhibited desires. It may also be combined with slow thinking, passivity, inertness, and apathy.

Euphoria may be induced by small amounts of alcohol, morphine, and other narcotics, by hypoxia (for example, mountain sickness), and often by severe bodily disease. It may also be a symptom of organic brain disease, such as the growth of tumors or progressive paralysis. It may be combined with signs of feeblemindedness. [29–1732–1]

EUPHUISM, a florid, elegant style in English literature of the last third of the 16th century, consisting entirely of rhetorical turns of phrase and figures of speech; its guiding principle was a syntactic, lexical, and phonetic parallelism (J. Lyly's novel *Euphues*, the source of the term, the novels of R. Greene, and the early comedies of Shakespeare). Euphuism helped enrich the language of English literature and bring about its rapprochement with other European literatures. Karamzinism in Russian literature from 1790 to the 1810's is an analogous development.

In a broader sense, euphuism denotes a grandiloquent style replete with tropes, metaphors, and periphrases. [29–1669–3]

EURIPOS, a strait in the Aegean Sea, dividing the central part of the island of Evvoia from the mainland of Greece. It is approximately 8 km long and has a length of 40 m at its narrowest point, where it is crossed by a bridge. The strait has strong tidal currents. The seaport of Khalkis (Chalcis) is situated on the Evvoian side of the strait. [29–1664–3]

EUROPEAN BLACKBIRD (*Turdus merula*), a bird of the family Turdidae of the order Passeriformes. The body length is about 25 cm. The male has shiny black plumage and a yellow bill. The female and the young of both sexes are brown. The European blackbird is distributed in Europe, Northwest Africa, and Asia. In the USSR the bird is found from the western borders eastward to the Southern Urals; its range also includes the Caucasus and the mountains of Middle Asia. The bird lives in deciduous and mixed forests, as well as in orchards and parks. In Western Europe it is common in cities. The song of the male is very beautiful. The nests are on the ground near tree roots, on stumps, or on bushes. A clutch contains four to seven light blue speckled eggs, which are incubated by both parents for 13 or 14 days. The diet consists of insects, worms, mollusks, berries, and small fruits. [29–306–4]

EURYBATHIC ANIMAL, an aquatic animal capable of existing at various depths. Eurybathic animals include benthic animals whose area of distribution ranges over various vertical zones, as well as pelagic animals that make extensive vertical migrations. Eurybathic animals are contrasted with stenobathic animals. Many eurybathic animals are widely distributed and are sometimes even cosmopolitan. [29–1662–8]

EURYBIONT, an animal or plant organism capable of surviving under substantial changes of environmental conditions. For example, eurytherms inhabiting the ocean littoral survive regular dry periods at low tide, extreme heat in summer, and chilling and

sometimes even freezing in winter. Euryhaline animals inhabiting river estuaries tolerate substantial fluctuations in water salinity. A number of eurybathic animals inhabit areas with a broad range of hydrostatic pressure. Many terrestrial inhabitants of temperate latitudes are capable of surviving large seasonal fluctuations in temperature.

Some species have a higher survival capability because of their ability to tolerate unfavorable conditions in a state of anabiosis. These include many bacteria, the spores and seeds of many plants, adult perennial plants of cold and temperate latitudes, wintering buds of freshwater sponges and bryozoans, the eggs of branchiopods, adult arthropods of the phylum Tardigrada, and some rotifer. Hibernation fulfills a similar function for certain mammals. The oocysts of parasitic protozoans and the larvae and ova of certain nematodes tolerate extreme freezing and drying and are resistant to many toxins; all of these factors make it possible for them to retain their viability for a considerable time.

The larvae of some insects and crustaceans, such as dragonflies and land crabs, are aquatic, while the adults are terrestrial. Thus, the environmental conditions tolerated by a species vary greatly in different stages of the life cycle, although each stage tolerates a narrower range of conditions. This is also true of certain parasitic worms, which in different stages of their life cycle parasitize invertebrates, fishes, and mammals and live in the external environment.

Sometimes adult individuals can survive greater changes in environmental conditions than can the young of the same species, for example, certain aquatic invertebrates and fishes. Certain widely distributed species have various populations adapted to life in regions with various conditions; thus, the survival capability of a species as a whole is greater than that of a particular individual or of groups of organisms at a specific stage of development. Eurybionts are usually distributed far more widely than stenobionts.

G. M. BELIAEV [29–1662–9]

EURYHALINE ANIMAL, an aquatic animal capable of tolerating substantial fluctuations in water salinity. The group includes many inhabitants of ocean littorals, river estuaries, brackish and ultrahaline waters, as well as migratory fishes. The opposite of euryhaline animals are stenohaline animals. [29–1663–1]

EURYPHAGY, the ability to consume varied vegetable and animal food, characteristic of humans and a number of animal species. Euryphagy is typical of several vertebrates, for example, the wild boar, Eurasian brown bear, and raven. Invertebrates characterized by europhagy include synanthropic species of cockroaches and termites. Euryphagy is an extreme degree of polyphagy. [29–1666–1]

EURYPTEROIDEA, a group of extinct aquatic arthropods of the class Merostomata that lived from the Ordovician through the Permian. The more or less spindle-shaped body measured 10–20 cm in length, although some, such as the genus *Pterygotus*, reached lengths of 1–1.8 m. The body was divided into a prosoma and an opisthosoma, which ended with a telson in the form of a spine or two lobes. On the prosoma there were simple and compound eyes and six pairs of extremities, of which the first, claw-shaped chelicerae, were piercing or prehensile and sometimes highly developed.

The Eurypteroidea embraced approximately 30 genera. They probably inhabited fresh or somewhat brackish waters and were predators. The study of the Eurypteroidea is important for an understanding of the evolution of arthropods, inasmuch as scorpions evidently descended from them during the Silurian, becoming the first arthropods to adapt successfully to life on dry land.

[29–1664–4]

EURYSTOMUS, a genus of birds of the family Coraciidae, order Coraciiformes. The beak is short, very broad at the base, and slightly humped at the top. The legs are short. The plumage is thick and stiff, mostly muddy green, dark blue, or violet. Of the three species, two are found in tropical Africa and Madagascar, and one in South and East Asia, New Guinea, and Australia.

In the USSR there is one species, the oriental roller or dollarbird (*Eurystomus orientalis*), which is found in the southern part of Khabarovsk Krai and in Primor'e Krai. The body measures approximately 30 cm in length. The plumage is blackish green, with dark blue wings and tail and a light spot on the wings that is clearly visible when the bird is in flight. The beak and feet are red. The oriental roller, a migratory bird, lives in tall deciduous forests with glades, especially in floodplains. It nests in hollows high above the ground. There are four to six white eggs per clutch. The young are naked and blind when they hatch, as are all young of the order Coraciiformes. The birds feed on insects, which they catch by flying about the trees in flocks, especially at dusk, or by lying in wait for them while sitting on a dry branch or on a treetop. More rarely they hunt for food on trees or on the ground. Sometimes the birds can be pests by catching bees near apiaries. [29–1230–2]

EURYTHERM, an animal capable of tolerating substantial fluctuations in environmental temperature. Eurytherms include most terrestrial animals that inhabit temperate latitudes, as well as many representatives of marine littoral fauna. Stenothermal animals are the opposite of eurythermal animals. [29–1665–1]

EURYTOPIC ORGANISM, a plant or animal capable of living in extremely varied habitats. Eurytopic organisms have high ecological valence, as opposed to stenotopic organisms. Their areas of distribution are usually extensive. The Scotch pine, for example, grows on the most varied substrates, including sandy soils, clayey loams, chalk, rock, and sphagnum marshes. It tolerates low winter and high summer temperatures and is found beyond the polar circle and occasionally in the steppe zone. The common reed and couch grass are also eurytopic.

Eurytopic animals include the black-bellied hamster and the common vole, which inhabit steppes, fields, meadows, and forest margins, as well as the wolf, fox, and many others.

The degree to which a species is eurytopic may vary. Species populations in the center of an area of distribution are eurytopic, while at the margins they usually become stenotopic. For example, the common vole in the forest-steppe inhabits watersheds and ravines, meadows, and steppe areas, while in the semidesert it inhabits only river valleys. [29–1665–2]

EUSTACY (also eustatism or eustatic change), a slow worldwide change in the level of the world ocean and the seas linked with it. Eustatic movements were first identified by E. Suess in 1888. A distinction is made between movements of the shoreline as a result of the formation of marine basins, when real changes in the level of the ocean occur, and movements of the shoreline as a result of tectonic processes, which cause apparent changes in the level of the ocean. Such changes, which result in local transgressions and regressions and are caused by different tectonic forces, were termed deleveling changes, whereas broad transgressions and regressions caused by fluctuations in the level of the actual water shell were called hydrokinematic changes by F. Iu. Levinson-Lessing (1893). A. P. Pavlov called (1896) negative movements of the shoreline geocratic movements and advances by the sea hydrocratic movements.

One of the hypothetical factors responsible for eustacy is the change in the total volume of water in the ocean in the course of the geological history of the earth, a change occurring as a result of the evolution of the continents. During the initial stages of the development of the earth's crust, juvenile waters constituted the single most important factor in eustacy. At later stages, the importance of this factor lessened. The volume of water stabilized in the Proterozoic, according to A. P. Vinogradov, and has not changed significantly in the hydrosphere since the Paleozoic. Somewhat important are the processes of sediment accumulation and volcanic flows on the ocean floor (sedimento-eustacy) and the resulting rise in the level of the world ocean.

Beginning with the Paleozoic, the tectonic factor acquired great importance (tectono-eustacy), causing changes in the volume of marine and ocean basins and alteration of the relief and structure of the ocean floor and adjacent continents. It appears that the main changes in the level of the world ocean are linked to the development of the system of midoceanic ridges and with the phenomenon of sea-floor spreading.

Along with tectono-eustacy, the climatic factor acquired considerable importance in recent geological times, in the form of glacio-eustacy. During the glacial epochs, when water was concentrated on the continents in the form of ice sheets, the level of the world ocean dropped by about 110–140 m; after thawing, glacier waters again flowed into the world ocean, raising its level by approximately one-third of the original level. The decrease in temperature and the associated change in salinity affected water density, and consequently the level of the world ocean in the high latitudes differed several meters from the level in the equatorial regions. The formation of the lowest terrace, 3–5 m, is linked to these factors. Planetary factors, such as changes in the earth's speed of rotation and the shifting of the poles, have also somewhat affected the mechanism of eustacy.

The study of the processes of eustacy is very important for historical geology and for gaining an understanding of the formation of the shelf zones, with which the formation of various minerals is linked.

EUTECTIC, a liquid system that, at a given pressure, is in equilibrium with solid phases whose number is equal to the number of components of the system. The liquid system may be a solution or ■ melt. According to the phase rule, the solidification of a eutectic system occurs at constant temperature, as does the solidification of pure substances. Hence, upon solidification, a eutectic mixture of solid phases having the same composition is formed. For a given system, the melting point of the eutectic mixture is lower than the melting point of a mixture of any other composition.

The eutectic reaction is characteristic of both metallic and nonmetallic systems whose components are completely soluble in one another in the liquid state but are only partly soluble or insoluble in the solid state (*see* BINARY SYSTEMS and TERNARY SYSTEM). In the phase diagram of a binary eutectic system whose components are not soluble in one another in the solid state (see Figure 1), the liquidus lines T_AE and T_BE of the pure components A and B, respectively, intersect at E, which is called the eutectic point. At E, the liquid L is simultaneously saturated in both components.

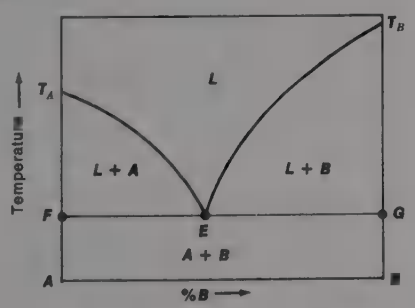

Figure 1. Phase diagram of ■ binary eutectic system whose components are not soluble in one another in the solid state: (*FEG*) eutectic-temperature line

In engineering, eutectics are widely used as, for example, casting alloys and solders. Cryohydrates, which are eutectic aqueous salt systems, are often used as freezing mixtures.

EUTECTOID, a eutectic that forms when a solid solution cools. In a phase diagram, a eutectoid point corresponds to the equilibrium of ■ solid solution whose phases have dissociated; the number of phases is equal to the number of components. A eutectoid point is analogous to a eutectic point in the case of the solidification of a liquid solution. An example of a eutectoid is pearlite in steel. [29–1667–2]

EUTROPHIC PLANTS, plants that grow well only on fertile soils rich in humus and minerals. Eutrophic trees include the English oak (*Quercus robur*) and the European ash (*Fraxinus excelsior*). Also eutrophic are herbs in oak groves, for example, goutweed (*Aegopodium podagraria*), dog's mercury (*Mercurialis perennis*), and sweet woodruff (*Asperula odorata*). Vegetation of the chernozem steppe, rich meadows, and bottomland marshes is eutrophic, as are almost all cultivated crops. (*See also* OLIGOTROPHIC PLANTS and MESOTROPHIC PLANTS.) [29–1668–1]

EUWE, MAX. Born May 5, 1901, in Watergrafsmeer. Dutch chess player. International grand master (1950); international-class official (1951).

Euwe graduated from the University of Amsterdam in 1924. He has a doctorate in mathematics and has been a professor at the University of Tilburg since 1964. Euwe was repeatedly champion of the Netherlands from 1921 to 1960. He won first place and prizes at several major international tournaments from 1923 to 1958. He became world champion in 1935 after defeating A. A. Alekhin but lost the return match in 1937. In the 1940's and 1950's he was a challenger for the world championship. He took part in a tournament for the championship in 1948 and in a challengers' tournament in 1953. In 1970–79 Euwe was president of the International Chess Federation.

EVACUATION. (1) The removal of wounded or sick personnel and prisoners of war as well as inoperative or superfluous equipment or captured matériel from combat areas to the rear.

(2) The withdrawal of troops from areas of military occupation, for military or political reasons or as the result of the conclusion of an agreement or a treaty.

(3) The removal of civilians, businesses, institutions, and property as well as valuables, such as works of art, from an area threatened by enemy attack or stricken by a natural disaster, such as a flood. [29–1632–2]

EVACUATION, MEDICAL, in the armed forces of the USSR, a series of measures taken by the military medical service to evacuate the wounded and sick from the field of battle or from a focus of mass destruction to medical facilities, called collecting stations, which provide interim medical treatment. The need for medical evacuation arises when conditions at the focus of destruction sharply limit the opportunities for immediate treatment, which is the most advisable from a medical point of view. Medical evacuation is an emergency procedure that affects the health of the evacuee, since it disturbs his rest and interrupts continuous medical care. As ■ result, medical evacuation is not conducted unnecessarily and is carried out with the utmost care.

Because its purpose is the timely provision of qualified and specialized medical care, medical evacuation involves the rapid transfer of the sick and injured to the evacuation stages where, according to the circumstances and the medical indications, pa-

tients will receive the most efficient treatment. Special medical transports and other available means, such as supply transports, are used for the evacuation.

Medical evacuation is closely linked to triage, which is the sorting of evacuees according to the medical indications and contraindications for evacuation, the type of transport to be used, the order of evacuation, and the destination. Coordination of transportation includes such measures as examining the evacuees before departure, adjusting bandages, and administering painkillers. When used to carry the injured and the sick, supply vehicles must be made warm and must be equipped with soft bedding and additional shock-absorbing devices. These and other modifications ensure relatively comfortable traveling accommodations for the evacuees.

Medical evacuation is a vital element not only of troop medical support, but also of the public assistance provided by the civil defense medical service. It is also used in natural disasters and in other catastrophes with large numbers of victims.

I. P. LIDOV [29–1632–3]

EVANGELISTA, CRISANTO. Born 1888 in Bulacan Province; died February 1942. Figure in the Philippine communist, working class, and national liberation movements. Founder of the Communist Party of the Philippines (CPP).

A typesetter by profession, Evangelista became secretary of the Printers' Union in 1906 and chairman of the union in 1918. In 1920 he led the first political strike of printers. He helped establish the Labor Party in 1924 and became one of its leaders; the activities of the party paved the way for the creation of the CPP in 1930. In 1927, Evangelista became vice-president of the Philippine Labor Congress—the country's largest trade union association, founded in 1913. In 1928 he headed the Philippine delegation to the Fourth Congress of the Red International of Trade Unions, which was held in Moscow. In 1929 he became general secretary of the Proletarian Union, a trade union that formed as a splinter group of the Labor Congress; from 1930 to 1933 he served as general secretary of the Central Committee of the CPP.

After spending the period from 1933 to 1936 in prison and exile for his revolutionary activities, Evangelista moved abroad. In 1938 he became chairman of the Central Committee of the CPP. Arrested by the Japanese police in January 1942, Evangelista died in prison.

EVANS, ARTHUR JOHN. Born July 8, 1851, in Nash Mills, Hertfordshire; died July 11, 1941, in Youlbery, near Oxford. British archaeologist.

Between 1899 and 1930 (with interruptions), Evans conducted excavations on the island of Crete, where he discovered the remains of a palace at Knossos. He thoroughly investigated the new Bronze Age culture, studying the palace and farm complexes, works of art, and clay tablets with pictographic inscriptions and with inscriptions in linear script. He designated the heretofore unknown pre-Hellenic culture as the Minoan culture and proposed a periodization of it. Using archaeological data, Evans reconstructed the state structure, religion, and developmental stages of Cretan society.

EVANS, RONALD ELLWIN. Born Nov. 10, 1933, in St. Francis, Kan. US pilot and astronaut. Captain in the navy.

Evans graduated from the University of Kansas in 1956 with a bachelor's degree in electrical engineering. Upon completion of courses in the Reserve Officers' Training Corps, he became a naval pilot. He graduated from the Naval Postgraduate School in Monterey in 1964 with a master's degree in aeronautical engineering.

Evans joined the National Aeronautics and Space Administration astronaut corps in 1966. From Dec. 7 to Dec. 19, 1972, as pilot of the Apollo 17 command module, he completed a flight to the moon with E. Cernan and H. Schmitt. Over a period of 147 hr 48 min, Evans completed 75 lunar orbits, providing support for Cernan and Schmitt's mission on the surface of the moon. On the return leg of the flight—a distance of 300,000 km from the earth—Evans spent 67 min outside the spacecraft. The entire flight lasted 12 days 9 hr 51 min. [29–1634–1]

EVANSTON, a city in the northern USA, in the state of Illinois, on Lake Michigan. A suburb north of Chicago. Population, 76,000 (1975). Local industry includes printing, instrument-making, and the production of pharmaceuticals. Evanston has a university. [29–1634–4]

EVANSVILLE, a city in the USA, in the state of Indiana. Population, 138,000 (1975; with the surrounding suburbs, 290,000). Evansville is a port on the Ohio River and a rail and highway junction. Local industry, which employed 40,000 persons in 1975, includes machine building and metalworking (the manufacture of parts for motor vehicles, engines, refrigerators, and electrical equipment) as well as food processing and the production of chemicals and furniture. [29–1634–3]

EVAPOROGRAPHY, a method of producing images of objects by making use of the thermal, usually infrared, radiation of the objects themselves. It was proposed by the German physicist M. Czerny in 1929.

In evaporography, either a layer of volatile liquid evaporates from a darkened membrane in a vacuum chamber or, vice versa, the liquid on the membrane condenses from vapor previously introduced into the chamber (Figure 1). The object is projected onto the membrane by a lens, and the image in the form of a liquid relief corresponding to the differences in evaporation or condensation at various points on the membrane is either viewed directly in interference colors or is photographed. The spectral region in which evaporography may be used depends on the properties of the lens and other elements of the apparatus and on the selection of the dark coating of the membrane; in practice, it is possible to produce images in the infrared region up to wavelengths of about 10 micrometers.

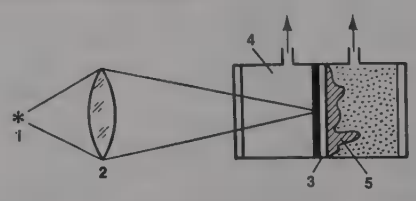

Figure 1. Diagram of the process for obtaining an image in evaporography: (1) object, (2) lens (usually infrared), (3) thin darkened membrane, (4) vacuum chamber, (5) liquid relief

Evaporography is primarily used for viewing and photographing in the dark, recording the infrared self-radiation of bodies,

the remote measurement of temperature and temperature distributions on the surface of an object (including applications in medical diagnosis), and the visualization of beams from infrared lasers.

Optiko-mekhanicheskaia promyshlennost', 1962, no. 11, pp. 27–34; 1964, no. 9, pp. 11–13. A. L. KARTUZHANSKII [29–1635–2]

EVARNITSKII, DMITRII IVANOVICH (also D. I. Iavornyts'kyi). Born Oct. 25 (Nov. 6), 1855, in the village of Borisovka, in what is now Kharkov Oblast; died Aug. 5, 1940, in Dnepropetrovsk. Ukrainian historian, archaeologist, ethnographer, folklorist, and writer. Academician of the Academy of Sciences of the Ukrainian SSR (1929); member of the Moscow Archaeological Society.

Evarnitskii graduated from the University of Kharkov in 1881. He taught at Moscow University, the University of St. Petersburg, and the University of Ekaterinoslav (now Dnepropetrovsk); at the last of these he established a subdepartment of Ukrainian studies. From 1902 to 1932 he was director of the museum of local lore in Ekaterinoslav, now known as the Academician D. I. Evarnitskii Dnepropetrovsk Historical Museum.

Evarnitskii was one of the first scholars to study the history of the Zaporozh'e cossacks; he published a large number of documents and was the author of *A History of the Zaporozh'e Cossacks* (vols. 1–3, 1892–97). He also gathered extensive folkloric material, much of which was published in the collection *Little-Russian Folksongs Collected Between 1878 and 1905* (1906). His scholarly works describe everyday life; some of his works, written during the prerevolutionary period, exhibit nationalistic tendencies.

Evarnitskii's novellas include *Our Lot is God's Will* (1901), *Not for His Own Sins* (1907), and *To the Seminary! To the Seminary! To the Seminary!* (1908). Evarnitskii also wrote satirical short stories and poems.

EVECTION, the greatest disparity—that is, deviation from motion according to Kepler's laws—in the moon's motion around the earth, caused by perturbation by the sun. Discovered by Hipparchus in the second century B.C., evection was detected by Ptolemy in the second century A.D. and was correctly explained by I. Newton. The change in the moon's longitude owing to evection reaches 1°16′26″ and varies with a period of approximately 31.8 mean solar days. The perturbing force that causes evection also changes the horizontal parallax of the moon periodically. [29–1639–3]

EVEN (also Lamut), the language of the Evens (Lamut). According to the 1970 census, Even is spoken by approximately 7,000 people along the coast of the Sea of Okhotsk and in neighboring regions. Together with Evenki and Negidal, it belongs to the northern group of the Manchu-Tungus languages. It has three dialect groups: eastern, western, and central. The eastern group includes the Ola dialect, on which the literary language is based.

Even is an agglutinative language in which grammatical relationships are expressed by the addition of suffixes to word stems. The Ola dialect distinguishes 18 consonants and up to 20 vowel phonemes, including i_a and i_e (phonemes that incorporate ■ glide whose articulation resembles that of the phoneme's primary, syllabic, element). Even exhibits palatal and labial vowel harmony. There are 13 nominal (noun) cases and a ramified system of possessive forms, which express personal, reflexive, and alienable possession.

Verbs are classified by conjugational features as verbs of action, verbs of state, and inchoative verbs. There are more than 15 aspects and six voices of the verb, as well as six participial forms, eight forms of adverbial participles, and negative and interrogative verbs. The attribute precedes the modified word and agrees with it in number and case. The vocabulary of the western dialects shows the influence of Yakut and Yukaghir, and the dialects of Kamchatka have undergone the influence of Koriak; Russian words began entering the Even language in the 17th century.

A Latin writing system was devised in 1931 and was used until 1936, when a Cyrillic alphabet was introduced.

EVEN AND ODD FUNCTIONS, in mathematics. The function $y = f(x)$ is said to be even if its value does not change when the sign of the independent variable changes—that is, if $f(-x) = f(x)$. If, however, $f(-x) = -f(x)$, then the function $f(x)$ is said to be odd. For example, $y = \cos x$ and $y = x^2$ are even functions, and $y = \sin x$, $y = x^3$ are odd functions. The graph of an even function is symmetric with respect to the y-axis, and the graph of an odd function is symmetric with respect to the origin. [29–360–1]

EVENKI (formerly, Tungus), a people of Siberia. The Evenki today inhabit a territory bounded on the west by the left bank of the Enisei, on the north by the tundra between the Enisei and Lena rivers beyond the arctic circle, in the east by the southern coast of the Sea of Okhotsk, and on the south by the Amur River and the northern raions of the Buriat ASSR. According to the 1979 census, the Evenki number 27,500 in the USSR; some live in Northwest China. The Evenki speak Evenki (Tungus).

The Evenki originally inhabited Transbaikalia and the Baikal Region, from which they appear to have migrated early in the second millennium A.D. to the area they now inhabit. By the 17th century, when they were incorporated into the Russian state, they had divided into exogamous patrilineal clans; they were nomadic and engaged in hunting, reindeer herding, and sometimes fishing. Although they became members of the Orthodox Church in the early 17th century, the Evenki retained various forms of pre-Christian worship, such as shamanism.

In 1930, Evenki National Okrug was created in Krasnoiarsk Krai (*see* EVENKI AUTONOMOUS OKRUG). Under Soviet power, the culture and economy of the Evenki underwent dramatic changes. A writing system was created, and illiteracy was stamped out. Many nomadic Evenki made the transition to a settled way of life. Land cultivation, livestock raising, and fur farming are being developed on kolkhozes and sovkhozes, along with the traditional occupations.

EVENKI (also Tungus), the language of the Evenki. According to the 1970 census, Evenki is spoken by 13,000 people in the USSR, mainly in Eastern Siberia—from the left bank of the Enisei to Sakhalin Island. There are approximately 9,000 speakers, including the Solon, in North China (Inner Mongolia and the Sinkiang-Uighur Autonomous Region) and Mongolia.

Evenki, together with Even and Negidal, belongs to the northern group of the Manchu-Tungus languages. It is divided into northern, southern, and eastern dialects and has, in addition, many subdialects, which are classified by phonetic features as the *ha*-subdialects, *se*-subdialects, and *še*-subdialects. The Solon subdialect is sometimes regarded as a separate language. Literary Evenki is based on the Nepa subdialect, called the Poligus subdialect since 1953, of the southern dialect.

Evenki has a complex, or "graded," law of qualitative and quantitative vowel harmony. It is an agglutinative language in which grammatical relations are expressed through the addition of suffixes to word stems. Evenki has a highly developed system of cases, verbal aspect and voice, and adverbial participles. The lexicon shows traces of close contacts with the Yakut and Buriat languages, and there are Russian loanwords. A Latin alphabet

was created in 1931, and a Cyrillic alphabet was introduced in 1937.

EVENKI AUTONOMOUS OKRUG (Evenkia), part of Krasnoiarsk Krai, RSFSR. Formed Dec. 10, 1930, and called Evenki National Okrug until 1977. Located in Eastern Siberia. Area, 767,000 sq km. Population, 15,000 (Jan. 1, 1977). Evenki Autonomous Okrug is divided into three raions. The administrative center is the urban-type settlement of Tura.

Natural features. Evenki Autonomous Okrug occupies the central part of the Central Siberian Plateau. The most elevated area is the Putorana Plateau, which reaches a maximum elevation of 1,701 m at Mount Kamen'. The greater part of the Tunguska Coalfield lies within the okrug, and the Nizhniaia Tunguska and Podkamennaia Tunguska regions contain deposits of iron ore, nonferrous metals, graphite, Iceland spar, petroleum, and natural gas.

The okrug has a distinctly continental climate. Winters in the okrug are long and harsh. The mean January temperature is −26.9°C in Vanavara, −36.8°C in Tura, and −37.2°C in Essei. Summers are short and warm, with a mean July temperature of 13.3°C in Essei, 15.5°C in Tura, and 16.6°C in Vanavara. Precipitation, which falls chiefly in summer, ranges from 300 mm per year in Essei to 500 mm per year in Kochumdek. The frost-free period ranges from 40 days in the north to 110 days in the south. There is extensive permafrost.

The principal rivers are right tributaries of the Enisei: the Nizhniaia Tunguska and Podkamennaia Tunguska. The Nizhniaia Tunguska flows for approximately 1,300 km within the okrug. Its principal tributaries are the left tributaries Ilimpeia, Nidym, Taimura, and Uchami and the right tributaries Kochechum, Vivi, and Tutonchana. The Podkamennaia Tunguska is more than 1,500 km long. Its principal tributaries are the right tributaries Tetere and Chunia and the left tributaries Vel'mo, Oskoba, Taiga, and Kamo. The Kureika River, which flows into the Enisei, rises in the okrug, as does the Kotui River and its tributary the Moiero. The most important of the okrug's numerous lakes are Essei, Vivi, Agata, Severnoe, and Niakshingda.

Mountain-forest podzolic soils predominate in the okrug. Mountain tundra soils are found in the northwest and sod-podzolic soils in the south. More than four-fifths (64 million hectares) of the okrug, most of which lies in the taiga subzone, is forest. Mixed dark coniferous forests of larch and spruce predominate in the south, in the Podkamennaia Tunguska region; light coniferous forests of larch, pine, and spruce grow in the interfluve of the Podkamennaia and Nizhniaia Tunguska rivers. In the Far North the taiga gives way to thin larch forests and moss-lichen tundra (one-tenth of the okrug).

Evenki Autonomous Okrug has a diverse fauna. Common fur-bearing animals include the sable, squirrel, and Siberian weasel. Other animals include the Eurasian brown bear, blue hare, wolverine, Siberian chipmunk, snow weasel, fox, wolf, reindeer, and moose; the muskrat has become acclimatized. Birds include the capercaillie, black grouse, hazel hen, and willow ptarmigan. The rivers and lakes are inhabited by such fish as sturgeon, taimen, sterlet, whitefish, broad whitefish, grayling, peled, burbot, pike, Eurasian perch (*Perca fluviatilis*), crucian carp, and cisco.

Population. According to the 1970 census, Russians make up more than 61 percent of the okrug's population, Evenki 25.2 percent, and Yakuts 6.6 percent. The average population density is 0.02 per sq km. The urban population, which constitutes 35 percent of the total population, is concentrated in the okrug's one urban-type settlement, Tura.

Historical survey. Early in the second millennium A.D. the Evenki settled the region they inhabit today. Their principal occupations were hunting, reindeer herding, and fishing; the most important game were such ungulates as wild deer and moose. Hunters used the bow and arrow and various homemade traps. In the first half of the 17th century the okrug was incorporated into Russia. This development was a historically progressive step: the Russians introduced the Evenki to firearms, and the indigenous population began using such foods as flour, tea, salt, and sugar. At the same time, the *iasak* (tribute) was imposed on the Evenki, and the people became subject to the rapacious policies of the tsarist government, which caused the death of a considerable part of the indigenous population.

The October Revolution of 1917 dramatically changed the life of the okrug's population. Kolchak's forces were driven out of Siberia in 1920. The Committee of the North, formed in 1924 under the All-Russian Central Executive Committee, rendered considerable assistance to the indigenous population.

In accordance with the Provisional Statute on Governing the Native Tribes and Peoples of the Northern Frontiers of the RSFSR, which was drafted by the Committee of the North, bodies of self-government were created for the peoples of the north: clan soviets, raion native councils, and raion native executive committees. Among the clan soviets formed in the okrug were the Murukta, Chirinda, Chapogir, and Pankagir clan soviets, all of which were subordinate to the Turukhansk raion executive committee.

In 1927, native raion executive committees were organized: the Ilimpeia, with headquarters at the Tura *kul'tbaza* (multipurpose cultural center), and the Baikit, with headquarters at the trading post of Baikit. In December 1930, Evenki National Okrug was formed, and the Evenki were granted equal political status with other peoples. In 1925 a decree of the Central Executive Committee of the USSR released the peoples of the north, including the Evenki, from national and local taxes, thereby greatly improving their economic position.

Collectivization of the Evenki's primitive economy began in the early 1930's: simple production associations were formed, which later were transformed into artels. Collectivization helped the indigenous population make the transition to a settled way of life. Land cultivation, animal husbandry, and fur farming, together with traditional occupations, underwent development at kolkhozes and sovkhozes.

Between 1930 and 1932, Soviet geologists discovered numerous deposits of coal, Iceland spar, building materials, and salt in the okrug, all of which provided a basis for industrial production. During the Great Patriotic War of 1941–45 the working people of the okrug increased the reindeer herd, the fish catch, and the fur output and collected a considerable amount of money and warm clothing for use in the country's defense. The Evenki serviceman Innokentii Petrovich Uvachan was posthumously awarded the title Hero of the Soviet Union.

During the postwar five-year plans, the Evenki people made important economic advances. The Evenki Autonomous Okrug was awarded the Order of the Red Banner of Labor in January 1971 and the Order of Friendship of Peoples in December 1972.

K. G. KUZAKOV

Economy. The principal branches of the economy of Evenkia are fur production and reindeer herding. The okrug, which accounts for 13 percent of the fur output of Krasnoiarsk Krai, produces sable, silver fox, ermine, squirrel, and muskrat furs. Hunting provides 55 percent, and cage fur farming 45 percent, of the furs produced. Silver foxes and blue arctic foxes are bred on fur farms.

The Evenki Autonomous Okrug has approximately one-third (45,000 as of Jan. 1, 1977) of the reindeer in Krasnoiarsk Krai and more than 1 million hectares of pastureland for the grazing of reindeer, primarily in the northern part of the okrug. In 1976 there were 11 sovkhozes, including four reindeer sovkhozes: Surinda, Tutonchany, Poligus, and Nidym. Dairy farming and the cultivation of potatoes and other vegetables are developing.

Industrial production is represented primarily by mining. Graphite is mined at the Noginskii deposit and shipped to Krasnoiarsk for processing. Iceland spar is extracted from deposits on the right bank of the Nizhniaia Tunguska and near the Nidym and Chambei rivers.

In 1975 the okrug had 2,200 km of waterways; the Nizhniaia Tunguska and Podkamennaia Tunguska rivers are navigable. The well-developed system of air transport connects the okrug

with various points, including Krasnoiarsk and numerous raion administrative centers. Reindeer are an important means of transport. S. T. BUDKOV

Education and cultural affairs. In the (1977–78) academic year 3,600 students were enrolled in the okrug's 31 general-education schools of all types, and 100 students attended the specialized secondary educational institution, a medical school. There are no higher educational institutions. In 1976, 1,500 children were enrolled in 27 preschool institutions, and there were 27 public libraries, with 169,000 copies of books and periodicals. An okrug museum of local lore is located in Tura, and there are three amateur theaters, in Tura, Baikit, and Vanavara. The okrug has 26 clubs, 28 motion-picture projection units, and three extracurricular institutions.

The okrug newspaper, *Sovetskaia Evenkiia*, has been published since 1933. Programs of All-Union Radio are transmitted, and krai and local radio programs are broadcast in Evenki and Russian for 11.5 hours daily. Programs of Central Television are relayed via the Orbita system for 12 hours daily.

Literature. Before the revolution the Evenki, then called the Tungus, had no writing system. Various genres of folklore were widespread among them. The first literary works came from Evenki writers among the students at the Leningrad Institute of the Peoples of the North in the late 1920's and early 1930's. A. M. Salatkin (1908–43) wrote the first collection of poems in the Evenki language—*The Taiga at Play* (1937)—and the epic folktale *Gegdalluken and Uglerikken* (1935). Soon there appeared the collection of poems *The Song of an Evenk* (1938), by A. N. Platonov (1912–39), and two works by G. Ia. Chinkov (1915–70): the collection of poetry *My Native Land* (1938) and the epic folktale *Garpanindia* (1939). N. Sakharov (1915–45), who fought in the Great Patriotic War of 1941–45 and died at Berlin, wrote poems about V. I. Lenin, the novella *Red Suglan* (1938), and stories about the new life among the Evenki.

A. Nemtushkin (born 1938) is the author of numerous literary sketches and the poetry collections *Morning on the Taiga* (1960) and *My Tokma* (1968). The poetry of such young writers as I. M. Udygir (born 1930), V. D. Lorgaktoev (born 1934), and S. N. Pikunov (born 1922) has been published in the national and local press. Many works by Russian and Soviet writers have been translated into Evenki, and the works of Evenki writers have been translated into various languages of the USSR.

EVEN LITERATURE, the literature of the Evens, or Lamut, a people living in Yakutia, in Magadan and Kamchatka oblasts, and in Khabarovsk Krai. Before Soviet power was established, Even literature existed only in the form of a rich oral tradition. In the early 1930's the first Even authors emerged among the students of the Leningrad Institute of the Peoples of the North. They were N. S. Tarabukin (1910–50), from Yakutia, and A. A. Cherkanov (born 1918), from Kamchatka. Tarabukin's collections, published in Even with a Russian parallel translation, include *Songs of the Taiga* (1936) and *The Flight of the Golden Girl* (1937); his autobiographical novella *My Childhood* (1936) also achieved popularity. Cherkanov is the author of the collection of poems *Hot Springs* (1937).

P. Lamutskii (real name, P. A. Stepanov [born 1920]), an expert on Yakut folklore, published collections of poems in the Yakut and Even languages, such as *Song of the Even* (1962) and *The Old Man's Children* (1970). Other noted writers in Yakutia include the Even poets D. E. Edukin (born 1931), V. S. Keimetinov (born 1936), and A. E. Nikulin (born 1937). The prominent Even poet V. D. Lebedev (born 1934) has written articles on language and folklore. Works by Even writers have been translated into various languages of the USSR.

EVENS (also Lamut), a people of northern Siberia living in several areas of Magadan and Kamchatka oblasts and east of the Lena River in the northern regions of the Yakut ASSR. According to the 1979 census, the Evens number 12,300; they speak the Even language.

The Evens, in origin and culture, resemble the Evenki. In the past they engaged chiefly in reindeer raising and hunting; the coastal Evens fished and hunted seals. Although the Evens formally became members of the Orthodox Church in the 19th century, they retained various forms of their pre-Christian worship, such as shamanism.

In the Soviet period, fundamental changes took place in the economy, culture, and everyday life of the Evens. A writing system was created in the 1930's, and illiteracy was eliminated. Many nomadic Evens made the transition to a settled way of life. Kolkhozes were established for livestock raising, for farming, and land cultivation, in addition to the traditional occupations.

EVENSK, an urban-type settlement and the administrative center of Severo-Evensk Raion, Magadan Oblast, RSFSR. Evensk is located on the shore of the Gizhiga Inlet of Shelikhov Gulf, 530 km northeast of Magadan. The settlement has a fish-processing plant. [29–1646–1]

EVENSMO, SIGURD. Born Feb. 14, 1912, in Hamar. Norwegian writer.

Evensmo took part in the resistance movement, which is the subject of his novel *The Fugitives* (1945; Russian translation, 1962). In 1942 he was imprisoned in a concentration camp, where he spent two years. Evensmo's realistic trilogy comprising *The Border* (1947), *The Bats* (1949), and *Homeward Bound* (1951) is a unique social history of Norway during the 1930's and 1940's. In his antiwar science-fiction novel *The Enigma of the Year Zero* (1957), he depicted the earth after an atomic catastrophe. In the screenplay for the film *The Africans* (1965) he criticized racial discrimination. Evensmo is the author of *The Grand Tivoli: The Norwegian Cinema Over the Past 70 Years* (1967), the first history of Norway's cinematography. In the book *Violence in Films* (1969), he attacked horror films. In collaboration with A. Brinchman he published *Norwegian Writers in War and Peace* (1968).

G. N. KHRAPOVITSKAIA [29–1647–1]

EVERETT, a city in the western USA, in the state of Washington; a northern suburb of Seattle. Population, 51,000 (1975). Everett is a port on Puget Sound. Its industries include the wood

products, plywood, paper, canning, and aerospace industries. Other economic activities include fishing and the processing of seafood. [29–1648–2]

EVERGLADES NATIONAL PARK, a park in the southern USA, in the state of Florida. It was created in 1947. As of 1977, it had an area of 566,796 hectares. The park has subtropical forests and mangrove forests, and it supports a broad range of animal life. Among the species of rare birds found there are the Everglades kite and the wood ibis. The manatee, cougar, and alligator are among the animals that have found refuge in the park. [29–1647–3]

EVERNIA, the genus of lichens of the family Usneaceae. The soft bushy thallus consists of narrow cylindrical or oblate branching blades. The upper surface is greenish gray, and the lower surface is whitish. The lichens contain everninic acid, usnic acid, and other lichen acids. There are about 15 species, growing on the trunks and limbs of trees and, less commonly, in the soil. The USSR has about eight species. Some species—including the most common, *Evernia prunastri*—are used in the perfume and drug industries. [29–1648–4]

EVERS, IOGANN FILIPP GUSTAV (also Johann Philipp Gustav Evers). Born July 4, 1781, in Westphalia; died Nov. 8 (20), 1830, in Dorpat (now Tartu). Russian historian. Honored member of the St. Petersburg Academy of Sciences (1826; corresponding member, 1809).

The son of a peasant, Evers graduated from the University of Göttingen in 1803. In 1810 he became a professor of Russian geography, history, and statistics at the University of Dorpat. In 1816 he published his study *History of the Russians*, which was written in German. In 1818, Evers became the rector of the University of Dorpat. In 1826 he published his important work *Ancient Russian Law in Its Historical Development*.

Evers regarded society as developing from the family to the clan and then from the tribe to the absolute state. This view had some influence on the statist school in Russian historiography. Evers' political views were reactionary.

M. P. PAVLOVA-SIL'VANSKAIA [29–1648–5]

EVERSMANN, EDUARD ALEKSANDROVICH. Born Jan. 23, 1794, in the village of Weringhausen, near Hagen, Westphalia, died Apr. 14, 1860, in Kazan. Russian naturalist. Corresponding member of the St. Petersburg Academy of Sciences (1842).

Eversmann was educated in Germany. He earned doctorates in philosophy and the liberal arts in Halle (1814) and in medicine and obstetrics in Dorpat (present-day Tartu, 1816).

In 1816, Eversmann moved to Russia and worked as a doctor in Zlatoust from 1818 to 1820. He later became interested in zoology and abandoned medicine. In 1828 he became professor of zoology and botany at the University of Kazan. As a member of the first Russian expeditions to Bukhara (1820–21) and Ustiurt (1825–26), Eversmann made collections of mammals, birds, and insects and described several new species.

[29–1648–6]

EVERT, ALEKSEI ERMOLAEVICH. Born Feb. 20 (Mar. 4), 1857; died May 10, 1926, in Vereia. Russian general of the infantry (1911).

Evert graduated from the Alexander Military School in 1876 and the Academy of the General Staff in 1882. He fought in the Russo-Turkish War of 1877–78. During the Russo-Japanese War of 1904–05 he became quartermaster general of the field staff in the Far East in October 1904 and chief of the field staff of the First Manchurian Army in March 1905.

Between 1906 and 1908, Evert was chief of the Main Headquarters and then a corps commander, and between 1912 and 1914 he served as commander of the Irkutsk Military District and as appointed ataman of the Transbaikal Cossack Host. Evert was appointed commander of the Fourth Army in August 1914, replacing General A. E. Zal'ts, and fought in the battle of Galicia (1914). He became commander in chief of the armies of the Western Front in August 1915. His incompetence as a military leader and his extreme indecisiveness were particularly apparent during the front's summer offensive in 1916 along the Vil'na (Vilnius) axis and in the vicinity of Baranovichi. Evert retired in March 1917, after the February Revolution, and lived in Smolensk and then Vereia, where he engaged in beekeeping. [29–1649–1]

ÉVIAN AGREEMENTS, accords between the government of France and the Provisional Government of the Algerian Republic, which was formed during the National Democratic Revolution in Algeria.

Signed on Mar. 18, 1962, in the city of Évian-les-Bains, France, the Évian Agreements sealed the victory of the Algerian people in the national liberation war against French colonialism. The agreements provided for a cease-fire on the territory of Algeria, a referendum in Algeria on the question of self-determination, and, should independence be chosen, the full sovereignty of the future Algerian state in its domestic and foreign affairs.

The accords also stipulated that the property of Frenchmen living in Algeria could not be confiscated without just compensation. In exchange, France undertook to provide economic, financial, technical, and cultural aid to Algeria on the basis of bilateral agreements, which were signed later as an extension of the Évian Agreements. French companies retained the right to extract and export petroleum.

A special declaration on military matters contained France's pledge to complete the withdrawal of its troops from Algeria in three years. (They were in fact withdrawn by July 1964.) By July 1, 1967, France had closed its military bases in Algeria, except for the base at Mers el Kébir, which was closed in February 1968.

In the latter half of the 1970's France and Algeria recognized that the Évian Agreements no longer reflected the actual state of their relations.

[29–1649–2]

EVLİYA ÇELEBİ. Born Mar. 25, 1611, in Istanbul; died there in 1682 or 1683. Turkish traveler, geographer, and writer.

For approximately 50 years, including time spent on military campaigns, Evliya traveled about many countries in Asia, Africa, and Europe. He visited the Northern Caucasus, the Ukraine, Moldavia, and the Crimea, and he sailed along the Don, Volga, and Iaik (now Ural) rivers. His travel sketches and diaries, which he edited at the end of his life, formed a ten-volume work called the *Book of Travels* (also known as *Chronicle of a Traveler*). Part of the work was published for the first time in 1843. Eight volumes were printed in the Arabic alphabet between 1898 and 1928, and the last two volumes were published in the Latin alphabet between 1935 and 1938.

Evliya's work is the longest memoir in classical Turkish literature. It is an important document of his epoch and contains a large amount of information about history, geography, and culture. It also includes numerous stories and legends from various countries and peoples, including peoples in what is now the USSR.

EVOLUTE AND INVOLUTE, concepts of differential geometry. The locus m of the centers of curvature of a plane curve l is called the evolute of l, and l is said to be an involute of m (see Figure 1).

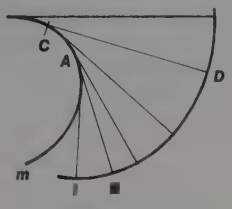

Figure 1

An involute l of a curve m is the curve described by the end B of the thread AB as it is unwound from m or wound on m. This construction of the involute makes clear the following properties of the evolute and involute: (1) The tangent CD at an arbitrary point C on the evolute is normal to the involute at the corresponding point D; consequently, an involute is an orthogonal trajectory of the tangents to the evolute. (2) Any orthogonal trajectory of the tangents to a curve m is an involute of m; m therefore has infinitely many involutes. (3) The difference between the radii of curvature AB and CD at the points B and D of an involute is equal to the length of the arc AC of the evolute. (4) The evolute is the envelope of the family of normals of an involute.

If a curve l is defined by the parametric equations $x = x(t)$ and $y = y(t)$, then the parametric equations of its evolute are

$$X = x + y' \frac{x'^2 + y'^2}{x''y' - y''x'}$$
$$Y = y + x' \frac{x'^2 + y'^2}{y''x' - x''y'}$$

An involute of a space curve is an orthogonal trajectory of the tangents of the curve.

EVOLUTION, in the broad sense, a synonym for development; in the narrower sense, one of the principal types of development —a slow, gradual, quantitative, and qualitative change—in contrast to revolution. In evolution, each new state of the object has, in comparison with the previous state, a higher level of organization and differentiation of functions. The distinction is made between individual evolution (of a certain individual object) and general evolution (of nature or life). In the process of evolution an important role is played both by internal factors and by external conditions of the object's existence. Changes occurring in the course of evolution are diverse.

Dialectical materialism regards evolution and revolution as interconnected and reciprocally conditioned aspects of development and opposes the absolutization of one or the other.

[29–1661–2]

EVOLUTION, BIOLOGICAL, the historical development of organisms. Evolution is determined by hereditary variation, the struggle for existence, and natural and historical selection. It results in the adaptation of organisms to their environment, changes in the genetic composition of entire populations and individual species, the formation of species and the extinction of less adapted ones, and the transformation of ecosystems and of the biosphere as a whole. The term "evolution" was first used in biology by the Swiss naturalist and philosopher C. Bonnet (1762). The causes and regularities underlying evolution constitute the subject matter of the doctrine of evolution. [29–1662–1]

EVOLUTION, DOCTRINE OF (biology), the body of knowledge of the historical development (evolution) of living nature. The doctrine of evolution encompasses the analysis of the development of adaptation, the evolution of ontogeny (or the individual development of organisms), the factors shaping evolution, and the concrete paths of the historical development (phylogeny) of individual groups of organisms and of the organic world as a whole. Based on the theory of evolution, it is also concerned with the origin of life and the origin of man. (*See* ONTOGENY; PHYLOGENY; and ORIGIN OF LIFE.)

History. The earliest ideas about the development of life, as expounded in the works of Empedocles, Democritus, Lucretius, and other ancient Greek and Roman philosophers, were essentially brilliant conjectures unsupported by biological facts. In the 18th century, transformism, the doctrine of variability of animal and plant species, emerged in biology, in opposition to creationism, a doctrine based on the concept of divine creation and the immutability of species (*see* TRANSFORMISM and CREATIONISM). The leading transformists of the second half of the 18th century and first half of the 19th—G. de Buffon and E. G. Saint-Hilaire in France, E. Darwin in England, J. W. van Goethe in Germany, and K. F. Rul'e in Russia—substantiated species variability mainly by two facts: the existence of transitional forms between similar species and the unity of the structural plan of the organisms of the major groups of animals and plants. However, the transformists did not examine factors responsible for the changes in species.

The first attempt to formulate an integral theory of evolution was made by the French naturalist J. B. de Lamarck, who set forth his ideas about the motive forces of evolution in *Philosophie zoologique* (1809). Lamarck believed that the transition from the lower forms of life to the higher forms—gradation—occurs as a result of the immanent and universal striving of organisms for perfection. He ascribed the diversity of species at every level of organization to the gradation-modifying influence of the environment. According to his first "law," the use of organs leads to their progressive development, while disuse leads to their reduction. According to his second law, the results of use and disuse of organs when sufficiently prolonged become hereditarily fixed and are then transmitted from generation to generation independently of the environmental influences that initially produced them (*see* LAMARCKISM and ACQUIRED CHARACTER). Lamarck's laws were based on the erroneous assumption that nature strives for perfection and that favorably acquired characters are heritable.

The true factors responsible for evolution were disclosed by C. Darwin, who thereby formulated a scientifically based theory of evolution, set forth in the book *The Origin of Species by Means of Natural Selection; or, the Preservation of Favored Races in the Struggle for Life* (1859). The motive forces of evolution, according to Darwin (*see* DARWINISM), are as follows: indefinite variation, the hereditarily caused diversity of organisms in every population of any species; the struggle for existence, in the course of which the less adapted organisms die or are prevented from reproducing; and natural selection, the survival of better adapted individuals, as a result of which useful hereditary changes accumulate and new adaptations arise. Lamarckism and Darwinism are diametrically opposite in their interpretation of evolution. The former explains evolution by adaptation, while the latter explains adaptation by evolution. Other ideas exist in addition to Lamarckism that reject the importance of selection as the motive force of evolution (*see* AUTOGENESIS, MUTATIONISM, and NOMOGENESIS). Advances in biology soon confirmed the validity of Darwin's theory. Therefore, Darwinism and the doctrine of evolution are often used synonymously in modern biology. Also similar in meaning is the term synthetic theory of evolution, which emphasizes the synthesis of the main tenets of Darwin's theory and of genetics and certain generalizations on evolution from other branches of biology.

Modern doctrine of evolution. Advances in genetics helped clarify the mechanism of the origin of indefinite hereditary variation, which provides the material of evolution. This phenomenon is based on stable changes in inherited structures—mutations (see MUTATION). Mutation is not directed: newly occurring mutations do not fit the existing environmental conditions and generally dis-

rupt already existing adaptations. Mutation acts as the principal material of evolution for organisms without a formed cell nucleus. Combinative variation, the combining of genes in the course of sexual reproduction, is very important for organisms whose cells do have a formed nucleus.

A population is the elementary unit of evolution (*see* POPULATION). The comparative isolation of populations results in their reproductive isolation—the restricted interbreeding between individuals of different populations (*see* ISOLATION). Reproductive isolation guarantees the uniqueness of the gene pool —the genetic makeup of every population—and, consequently, the possibility of its evolving independently (*see* GENE POOL). The biological mixture of individuals constituting a population determined by combinative and mutational variation is manifested in the struggle for existence. Some individuals die, while others survive and reproduce. As a result of natural selection, the new mutations combine with the genes of already selected individuals, the phenotype alters, and new adaptations arise. Hence, selection is the principal motive force of evolution and the factor responsible for new adaptations, the transformation of organisms, and speciation.

Selection may be manifested in different forms: stabilizing selection guarantees the preservation of already formed adaptations under unchanged environmental conditions; directional selection leads to the formation of new adaptations; and disruptive selection gives rise to polymorphism when considerable changes occur in the habitat of a population. In the modern doctrine of evolution, the conception of the factors of evolution was enhanced by the identification of the population as the elementary unit of evolution, by the theory of isolation, and by the development of the theory of natural selection. Isolation as a factor responsible for increasing the diversity of living forms underlies modern thinking on speciation and species structure (*see* SPECIATION). Allopatric speciation, caused by the distribution of a species and by the geographic isolation of distant populations, has been studied in greatest detail thus far. Less attention has been focused on sympatric speciation, caused by ecological, chronological, or ethological (behavioral) isolation (*see* ALLOPATRIC DISTRIBUTION OF ORGANISMS and SYMPATRIC DISTRIBUTION OF ORGANISMS).

The evolutionary processes that occur within a species and culminate in speciation are often combined under the general term "microevolution" (*see* MICROEVOLUTION). Macroevolution is the historical development of groups of organisms (taxa) of categories above the level of species. The evolution of taxa higher than species is the result of speciation originating under the influence of natural selection. However, the use of different time scales (the evolution of major taxa encompasses many stages of speciation) and research methods (use of data from paleontology, comparative morphology, embryology, and other sciences) helps to reveal patterns that are not detectable in the study of microevolution. The most important objectives of macroevolution are to analyze the relationship between individual development and the historical development of organisms and to determine the regularities of phylogeny and the main directions of the evolutionary process.

In 1866 the German naturalist E. Haeckel formulated the biogenetic law, according to which the stages of phylogeny of a taxonomic group are recapitulated in ontogeny (*see* BIOGENETIC LAW). Mutations are reflected in the phenotype of the adult organism if they alter the processes of its ontogeny. Therefore, natural selection among adult individuals leads to the evolution of the processes of ontogeny—the interrelations between developing organs, which I. I. Shmal'gauzen called ontogenetic correlations. The reorganization of the system of ontogenetic correlations caused by directional selection gives rise to phylembryogeny, by means of which new traits of organisms are formed in the course of phylogeny. If the changes occur in the organ's final stage of development, the organs of the ancestors continue to evolve further (anaboly). Deviations in ontogeny may also occur in the intermediate stages, resulting in the restructuring of organs (deviation). Changes in the formation and development of the early rudiments may give rise to organs not present in the ancestors (archallaxis). However, the evolution of ontogenetic correlations under the influence of stabilizing selection results in the preservation of only those correlations that most reliably safeguard the processes of ontogeny. These correlations are the recapitulations —duplications of the phylogenetic states of the ancestors in the ontogeny of the offspring—and they confirm the biogenetic law.

The direction of phylogeny of every taxonomic group is determined by its actual relation to the environment in which the taxon and its organization are evolving. The divergence of traits that arises among two or more taxa with a common ancestor is due to differences in environmental factors. It begins at the population level, leads to an increase in the number of species, and continues at taxonomic levels above the level of species. The taxonomic diversity of living organisms is caused by divergent evolution. Parallel evolution, which is less common, occurs when primary divergent taxa remain under similar environmental conditions and develop similar adaptations based on a similar organization inherited from the common ancestor. Convergence occurs when unrelated taxa adapt to identical conditions. Biological progress can be achieved by a general rise in the level of organization responsible for adapting organisms to environmental conditions that are broader and more varied than the conditions under which their ancestors lived. Such changes, aromorphoses, rarely occur and must give way to allomorphoses—divergence and adaptation to more specific conditions in the new habitat (*see* AROMORPHOSIS and ALLOMORPHOSIS).

The formation of narrow adaptations in the phylogeny of a group results in specialization. Shmal'gauzen distinguished four main types of specialization—telomorphosis, hypomorphosis, hypermorphosis, and katamorphosis—which, although differing in the nature of the adaptations, all result in a slowing of the rate of evolution (*see* EVOLUTION, RATE OF) and a decrease in evolutionary flexibility as a result of the loss of multiple functions by the organs of specialized animals (*see* TELOMORPHOSIS; HYPOMORPHOSIS; HYPERMORPHOSIS; and KATAMORPHOSIS). If the environmental conditions remain stable, the specialized species can exist indefinitely. This explains the occurrence of "living fossils," such as the many mollusk and brachiopod species that have existed from the Cambrian to the present day. If the living conditions change abruptly, the specialized species die out, while the more adaptable ones manage to adapt to the changes.

The doctrine of evolution and especially its theoretical core, the theory of evolution, serve as an important scientific foundation of dialetical materialism and a basis for modern biological methods.

A. S. SEVERTSOV [29–1657–1]

EVOLUTIONARY MORPHOLOGY AND ANIMAL ECOLOGY, INSTITUTE OF (full name, A. N. Severtsov Institute of Evolutionary Morphology and Animal Ecology of the Academy of Sciences of the USSR), the leading Soviet scientific research institution engaged in the study of the phenomena of the evolution-

ary process and animal ecology, as well as a center for research in morphology. Located in Moscow, it was established in 1967 on the basis of the Institute of Evolutionary Morphology (founded 1935). The laboratories of experimental zoology (founded 1893 by A. O. Kovalevskii) and evolutionary morphology (founded 1930 by A. N. Severtsov) were incorporated into the institute and were contributing factors in determining its fields of specialization.

The institute has (1977) 20 laboratories, including laboratories of soil zoology and experimental entomology, the morphology and ecology of higher vertebrates, problems of domesticating animals, radioecology, the ecology of communities of terrestrial invertebrates, the behavior of lower vertebrates, problems of fish orientation, bioacoustics, and bird orientation and navigation (with a tagging center). It has a number of research groups, including the Man and the Biosphere, historical ecology, and biocybernetics groups.

The institute administers the Glubokoe Ozero Biological Station (organized 1891; Ruza Raion, Moscow Oblast), the Kostroma Taiga Experiment Station (organized 1977; Manturovo Raion, Kostroma Oblast), Utrish Marine Station (organized 1977; Anapa Raion, Krasnodar Krai, RSFSR), the Varzob Mountain Station (organized 1977; Tadzhik SSR), the Mukachevo Experimental Facility (organized 1959; Transcarpathian Oblast, Ukrainian SSR), the Chernogolovka Experimental Facility (organized 1975; Noginsk Raion, Moscow Oblast), a vivarium, and an electron microscopy unit.

The institute conducts research in the evolution of the structure, organs, and tissues of animals, the evolution of ontogeny, intraspecific variation of animals, changes resulting from domestication, the phylogenetic basis of animal behavior and orientation, patterns of animal population dynamics and biomass, and the evolution of biogeocenoses.

V. E. SOKOLOV and N. G. RUBAILOVA [29–1660–1]

EVOLUTIONARY PHYSIOLOGY, a branch of physiology that studies the various functions of animals in the formative stage and in the course of historical development. Evolutionary physiology investigates the evolution of functions, that is, the processes by which the functions are formed and change under the influence of external and internal factors. It also deals with functional evolution in an attempt to answer why new functional relations arise and develop in a particular way.

The emphasis on evolution in Russian physiology is linked with the research of I. M. Sechenov, N. E. Vvedenskii, and I. P. Pavlov. The term "evolutionary physiology" was coined by A. N. Severtsov in 1914. The person most responsible for the creation of Russian evolutionary physiology is L. A. Orbeli, who devised the scientific method for studying it, defined the main objectives, and outlined (in the 1920's) the direction in which it should develop.

Orbeli, A. G. Ginetsinskii, P. K. Anokhin, and others formulated a number of general principles of functional evolution: (1) in the course of development and increasing complexity of the level of organization and establishment of new relations in the organism, the old functional relations do not disappear without a trace but remain suppressed, masked by phylogenetically younger functions; (2) the controlling influence on the nervous system increases as the organism develops; and (3) the various functional systems mature at different times in the course of individual development (*see* HETEROCHRONISM).

The study of the evolution of the central nervous system (A. I. Karamian) was closely linked with the investigation of the formation and development of conditioned reflexes in animals (E. M. Kreps, L. G. Voronin, D. A. Biriukov). Comparative and developmental physiology have long been successfully developed in Britain, the United States, Denmark, Czechoslovakia, and other countries, but the standardization of research methods and the establishment of evolutionary physiology as the modern stage of physiology, based on the historical principle, are the accomplishment of Russian science.

Evolutionary physiology makes use of the findings and advances of general physiology, biochemistry, comparative morphology, genetics, and other sciences, as well as the research methods of comparative, developmental, and ecological physiology. Comparative physiology makes it possible to compare and clarify the characteristics and specific regularities of the development of physiological functions in animals belonging to different taxonomic groups. Research on functions in the embryonic and postnatal stages of ontogeny has made it possible to establish the mechanisms governing the emergence and development of functions. Evolutionary physiology also makes use of clinical data, comparing symptoms of diseases with phenomena observed in the ontogenetic or phylogenetic development of the organism. Linked to clinical research are special experimental techniques that enable scientists to disconnect organs and tissues artificially from the mechanisms that control them, as well as from the different levels of the controlling mechanisms themselves. The development of the evolutionary trend in physiology has made it possible to uncover new patterns in the functional evolution of the brain and various systems of the organism and to reveal common principles underlying the evolution of the structure and functions of the sense organs, the evolution of the musculoskeletal system, and the maintenance of homeostasis in an organism. An important objective of modern evolutionary physiology is to determine the adaptative changes that occur in functions and to study higher nervous activity in humans as it forms and develops.

In the USSR, research in evolutionary physiology is primarily conducted at the I. M. Sechenov Institute of Evolutionary Physiology and Biochemistry (Leningrad), the A. N. Severtsov Institute of Evolutionary Morphology and Animal Ecology (Moscow), the N. K. Kol'tsov Institute of Developmental Biology (Moscow), and other institutes administered by the Academy of Sciences of the USSR. All-Union conferences on evolutionary physiology and biochemistry have been held periodically since 1956. Research results are published in the *Zhurnal evoliutsionnoi biokhimii i fiziologii* (since 1965) and in other journals of physiology.

E. M. KREPS [29–1655–1]

EVOLUTIONARY PHYSIOLOGY AND BIOCHEMISTRY, INSTITUTE OF (full name, I. M. Sechenov Institute of Evolutionary Physiology and Biochemistry of the Academy of Sciences of the USSR), the leading scientific research institution involved in the study of the physiological, biochemical, and structural foundations of the evolution of functions. It was organized in 1956 at the initiative of the academician L. A. Orbeli in Leningrad on the basis of the Laboratory of Evolutionary Physiology, established by Orbeli in 1954. It was called the I. M. Sechenov Institute of Evolutionary Physiology until 1964.

The institute has (1977) 23 laboratories under the departments of the following subject areas: the evolution of the central nervous system, comparative physiology and morphology of afferent systems, the development of autonomic functions, the evolution of cholinergic systems, and evolutionary biochemistry. The institute conducts research on the functional evolution of the central and autonomic nervous systems, the biochemical evolution of the brain, the evolution of the structure, function, and biochemistry of the receptor apparatus, the evolution of endocrine functions, the development of kidney function and water-salt metabolism, the functional and biochemical evolution of the contractile apparatus, the evolution of the neuron and neurosecretory system, the evolution of higher nervous activity in children, and evolutionary regularities in the pathology of the human nervous system.

The studies of the staff members are published primarily in the *Zhurnal evoliutsionnoi biokhimii i fiziologii.* [29–1661–1]

EVOLUTIONIST SCHOOL, in ethnology, a trend that emerged during the formative period of ethnology as a science (second half of the 19th century) under the influence of the doctrine of evolution. Its chief representatives were J. Lubbock, J. McLennan, E. Tylor, and J. Frazer in Great Britain, A. Bastian, W. Wundt, and J. Lippert in Germany, L. H. Morgan in the United States, and D. N. Anuchin, M. M. Kovalevskii, the Kharuzins, and L. Ia. Shternberg in Russia.

The evolutionists considered the universal law of social development to be the evolution of culture from lower forms to higher forms, from savagery to civilization. They combined the progressive idea of the cultural unity of the human race and the use of ethnographic data, as well as mythological, archaeological, and other historical sources, to reconstruct early history with the mistaken assertion of the total similarity of the historical development of different peoples. They viewed history as the sum of the independent evolutions of separate elements of culture and social structure. Most proceeded not from a materialist understanding of the general laws of human history but from the idealist thesis of the "psychic unity" of the human race and its "elementary ideas" (Bastian), which form the basis of every culture. Morgan came close to the materialist explanation of history by examining social progress in relation to the development of the means of existence.

The classics of Marxism used Morgan's works and the works of other evolutionists in formulating a truly scientific conception of prehistory. Beginning in the late 19th century, the main theses of the evolutionist school were revised in bourgeois ethnology (K. Starke and E. Westermarck). (*See* CULTURAL HISTORY, SCHOOL, OF, and FUNCTIONALISM.) In the mid-20th century, a trend has emerged in American ethnology that makes use of the principal theses of the evolutionist school and correlates them with the latest scientific findings (L. White, J. Steward's neo-evolutionism).

EVORON, a lake in the basin of the lower Amur River, in Khabarovsk Krai, RSFSR. Lake Evoron has an area of 194 sq km and a depth of 2–3 meters. It extends 30 km from north to south and has a maximum width of 12 km. The western and southern shores are elevated and forested, whereas the others are low-lying and swampy. Fed by snow and rain, the lake is at its highest level in the spring and early summer. It freezes over in late October or early November, and the ice breaks up in May. The Evur River flows into Lake Evoron, which is fished commercially.
[29–1662–4]

EVORSION, erosion caused by vortices and eddies formed by falling streams of water, leading to the formation of potholes.
[29–1662–3]

EVVOIA (also Euboea), an island in the Aegean Sea, off the shore of the Balkan Peninsula, with which the island is connected by a bridge. Evvoia belongs to Greece. Together with its small offshore islands, it has an area of 3,908 sq km, and it measures 170 km from northwest to southeast. As of 1971, it had a population of 165,400. Elevations reach 1,743 m in the Dirphys, and karst is well developed. Evvoia has Mediterranean shrubs and forests. Agriculture includes animal husbandry and the cultivation of subtropical crops. There are magnesite deposits at Limne. The capital of the island is the city of Khalkis (Chalcis).
[29–1636–2]

EWALD, JOHANNES. Born Nov. 18, 1743, in Copenhagen; died there Mar. 17, 1781. Danish writer.

In his early works Ewald followed the examples of French classicism, for example, his tragedy *Adam and Eve* (1769). He later turned to themes drawn from Scandinavian mythology and history. Ewald's dramas *Rolf Krage* (1770) and *Balder's Death* (1775) prepared the way for the romantic national drama. The heroes of his tragedy *The Fishermen* (1779) are simple working men. Ewald wrote an autobiographical narrative *The Life and Opinions of Johannes Ewald* (1774–78). In his unfinished philosophical novel *The History of Mr. Panthakak* (begun 1771), he harshly criticized the concept of Enlightenment optimism. He also published odes and cantatas, as well as lyric poems. Ewald's song "King Christian Stood by the Lofty Mast" became Denmark's national anthem.

EWE (self-designation, *Ewegbe*), a people related to the Fon. The Ewe inhabit southeastern Ghana and southern Togo. According to a 1975 estimate, they number 2.55 million; they speak a Kwa language. Ancient beliefs involving ancestor and nature worship are widespread among the Ewe, although some profess Islam or Christianity. Before European colonization in the 19th century, land cultivation, handicrafts, trade, art, and folklore had reached a high level of development. In modern Ewe society, capitalist relations are combined with vestiges of clan and feudal relations. The Ewe engage primarily in land cultivation, their chief crops being maize, yams, cassava, and sweet potatoes; cocoa beans, oil-palm products, and cotton are produced for export.

[29–1639–1]

EWE, the language of the Ewe people, spoken in southeastern Ghana and in southern Togo and Benin (Dahomey). According to a 1972 estimate, there are approximately 2 million speakers of Ewe, which is a Kwa language, of the Niger-Kordofanian language family. Ewe comprises three dialect groups: the western, central, and eastern. The western is made up of Anglo (Awuna) and the "interior" dialects; the central is made up of Wachi, Adja, and Gen; and the eastern is made up of Gun, Fon, and Mahi.

Ewe is distinguished by a rich vowel system: it has seven vowels, five of which have nasalized pairs. All vowels have three degrees of length, and there are numerous diphthongs. Consonants include the bicentral labiovelars *gb* and *kp*, and there is an opposition between bilabial and labiovelar *f* and *v*. Ewe has a dental and retroflex *d* and clusters of obstruents and resonants. Lexically distinctive tones exhibit phonological opposition.

Ewe is an isolating language. Simple words are mainly monosyllabic, and composition and reduplication are used extensively. There are derivational prefixes. The person and number of the verb are expressed by subject pronouns; aspect and tense, by special markers and by reduplication. The attribute precedes the word it modifies.

A Latin alphabet was devised in the late 19th century. Ewe literature is published mainly in the Anglo dialect.

EXA-, a prefix used to form the names of units of measure equal to 10^{18} of the original unit. It was adopted in 1975 by the 15th General Conference on Weights and Measures. The symbol is E.
[29–1890–2]

EXACUM, a genus of annual or perennial herbaceous plants of the family Gentianaceae. The flowers are white, lilac, dark blue,

or purple-violet; the inflorescence is a panicle. The fruit is a two-valved globose capsule. There are about 35 mainly tropical species, growing in India, East Asia, the Malay Archipelago, and the island of Socotra. Some ornamental species are raised in conservatories. Popular ornamentals include *E. affine*, which has numerous lilac flowers with yellow anthers, and *E. zeylanicum*, which has large azure flowers. [29–1753–4]

EXALTADOS, the members of a party of left-wing liberals in Spain during the revolution of 1820–23; also known as the New Liberals or the Liberals of 1820.

The *exaltados* included bourgeois and petit bourgeois urban elements, as well as certain officers, officials, and nobles. Their leaders were Flores de Estrado, Moreno Herra, Romero Alpuente, and R. Riego y Nuñez. Many of the *exaltados* were Masons. The extreme left-wing elements of the party broke away from the *exaltados* and formed the independent group known as the Comuneros.

The *exaltados* formed a government on Aug. 5, 1822. In May 1823 they achieved the passage of a law they had proposed to abolish seignorial rights, but they were unable to carry out the law because of intervention by France. The government of the *exaltados*, together with part of the Cortes and King Ferdinand VII, whom the *exaltados* held captive, moved to the Isla de León, where it surrendered on Sept. 30, 1823. After the outbreak of the revolution of 1834–43, many of the former *exaltados* joined the Progressive Party. L. V. PONOMAREVA [29–1890–3]

EXALTATION, an excited, rapturous state; in physiology, a transient period of heightened sensitivity of nerve and muscle tissues that gives way to a period of lowered, subnormal sensitivity. [29–1751–2]

EXAMINATION (Russian, *ekzamen*), in the USSR, a comprehensive survey of the knowledge of a student or of a person graduating from or entering an educational institution. Unlike tests (*zachety*), examinations—both oral and written—are always graded.

After the October Revolution of 1917 the system of examinations that existed in Russia was abolished. The following examinations were made compulsory in the 1930's: annual promotion examinations in general-education schools, beginning in fourth grade; admission, or entrance, examinations for higher and specialized secondary educational institutions; and semester final and state graduation examinations in higher and specialized secondary educational institutions.

In 1944 graduation examinations were instituted for students of incomplete secondary and secondary schools. According to the Statute on the Secondary General-Education School of 1970, the procedure for administering examinations in secondary general-education schools is determined by the ministries of education (or public education) of the Union republics. Compulsory graduation examinations are given in the eighth and 10th (or 11th) grades. Students who pass them receive a certificate of completion of an eight-year school or a certificate of secondary education. Promotion examinations may be instituted for the fourth through seventh grades and the ninth (or 10th) grade by the ministry of education (or public education) of a Union republic. There may be no more than three such examinations per grade. The certificate of completion of an eight-year school and the certificate of secondary education may also be received through the system of extramural education.

In higher and specialized secondary educational institutions, the time and procedure for administering competitive entrance examinations, semester finals, and state graduation examinations are determined by the Ministry of Higher and Secondary Specialized Education of the USSR according to the type of school. Students who have passed all tests are permitted to take the semester final examinations, and students who have passed all the semester finals may take the graduation examinations.

At many institutions of higher learning and at many technicums, defense of a diploma project or diploma thesis replaces state examinations in special disciplines. Vocational-technical schools and vocational courses give qualifying examinations for certain ratings, or ranks, in various lines of work. In addition to qualifying examinations, secondary vocational-technical schools also give graduation examinations in general-education subjects.

EXANTHEM, VESICULAR, an acute viral disease of swine, characterized by fever and the formation of numerous vesicles on the skin. Swine of all ages are susceptible to the causative agent of the disease. The source of the agent is diseased swine. Infection occurs through contact with diseased animals or through fodder contaminated with their excretions.

Symptoms include elevated body temperature, decreased appetite, salivation, and the appearance of numerous vesicles on the oral mucosa, snout, and udders. The vesicles open, exposing a tender surface. If the extremities are affected, there is edema and lameness. In piglets there may be pneumonia, inflammation of the intestinal tract, and death. Treatment consists in the application of disinfectant and astringent solutions to affected areas. Preventive measures include the observance of sanitary conditions while transporting swine and trading in swine or pork. [29–1752–4]

EXARATION, the glacial destruction of the rocks that make up the bed of the glacier and the removal of the broken material (detached masses, boulders, pebbles, sand, clay, and so on) by a moving glacier. Exaration brings about the formation of glacial troughs, lake basins, sheepback rocks (roches moutonnées), glacial scarrings, and striations. In the course of destruction, the rocks are smoothed, ground, and polished. [29–1753–1]

EXARCHATE, a governorate in Byzantium from the late sixth to the late seventh century. The early exarchates were established in the western Byzantine Empire in lands retaken from the barbarians, the first exarchates being those of Ravenna and Carthage. Since the special circumstances attending such regions required the creation of a militarized and centralized government, exarchs headed not only the military forces but also the civil administration. The exarchate is sometimes regarded by Byzantine scholars as the prototype of the theme. [29–1753–3]

EXCAVATION, the process of removing rock or earth from a solid, broken, or unconsolidated layer by means of an excavator, bulldozer, scraper, or similar machine. In earthwork practice, the term "excavation" may also include the entire work cycle, that is, digging, transportation, and dumping of the earth with excavators.

Soft, loose, and dense rock is usually excavated directly from the solid formation by successive removal of layers of ground; rock that has been broken up beforehand is excavated from piles or loosened layers. Three types of excavation are distinguished according to the mutual position of the face and the horizon on which the machine is working: the face may be above or below the machine horizon, or a combination of the two arrangements may be used. Because digging is the principal component of the process of excavation, it is conventional to describe the process with respect to the specific resistance to digging. This quantity is affected by the physicomechanical properties of the rock or earth, the type of excavating machine used, the design and dimensions of the working member, and the procedure followed in working the face.

EXCAVATOR, the principal type of machine designed to dig solid, soft rock or earth or fragmented hard rock and to load the ma-

terial into hauling units, such as motor vehicles and railroad cars, or deposit it in spoil banks. In the USSR, excavators handle approximately 35 percent of the earthwork in construction and more than 80 percent of the open-pit mining excavations; the total annual volume of excavations in the USSR (1976) is 15 billion cu m.

In the USSR excavators are divided into two groups according to the principle of operation: single-bucket excavators (power shovels) with discontinuous, or cyclic, action and multibucket excavators with continuous action. In the first group, all the major operations in a cycle are performed in a fixed sequence; in the second group they occur simultaneously.

Single-bucket excavators. The operating cycle of the widely used class of single-bucket excavators includes cutting or digging the ground as the bucket is simultaneously filled, moving the full bucket to the unloading point, unloading the bucket, and returning the bucket to the face. Depending on the power and the type of excavator and on the working conditions, the duration of the cycle ranges from 12 to 80 sec. The output of a single-bucket excavator with a bucket capacity of 1 cu m ranges from 100,000 to 350,000 cu m per year, or from 80 to 180 cu m/hr. Such machines are used for excavating any type of earth, including very hard and inhomogeneous earth containing large, solid inclusions. When used to work softer earth, they can be equipped with buckets of larger capacity. Hard rock and frozen earth are broken up (usually by blasting) before the excavators are used.

Single-bucket excavators are classified according to running gear as crawler-mounted, wheeled, walking, rail, floating, and combination rubber-tire-crawler types. They may be driven by a single engine or feature composite and/or individual drives for all operating equipment. The power unit may be an internal-combustion engine (diesel engines or sometimes carburetor or producer-gas engines) with electric, hydraulic, pneumatic, or combination-type motors. Single-bucket excavators may also be classified according to the type of control—manual, hydraulic, pneumatic, electrical, and composite types—and according to the type of operating equipment used—a bucket with a hinge and slide connection to the boom (forward dipper), a bucket with a hinge connection to the boom (backhoe), and a bucket with a flexible connection to the boom (dragline, clamshell, and other types). The most common type is the forward dipper (Figure 1,a); it may have any power rating and a bucket capacity up to 153 cu m (*see* POWER SHOVEL). Forward dippers designed to load the excavated material into hauling units or deposit it in spoil dumps are best suited to working mineral deposits and digging foundation pits, mainly in hard rock and rocky earth as well as in solid soils of average hardness.

The backhoe (Figure 1,b) is used to dig narrow trenches 0.7–1.5 m wide and up to 8 m deep, especially trenches with vertical walls (for laying sewer systems, oil pipelines, and foundation structures in hard and rocky earth) and small foundation pits.

The operating equipment of a dragline (Figure 1,c) comprises a boom and a bucket, which is suspended from the boom by means of hoisting and hauling (dragline) cables. The unit usually removes earth from a level below that on which it rests. Buckets of various capacities are used—more than 10 cu m for rocks that have been broken up beforehand. The duration of a cycle is usually 10 to 20 percent longer than that of a forward dipper. Approximately 40 percent of all excavators are operated with dragline equipment. Those that move in steps are called walking draglines.

Clamshell equipment (Figure 1,d) is used for loading operations, digging foundation pits with vertical walls, and working underwater. Plow units (Figure 1,e) are suitable for grading operations, removing pavements, and the like. Some excavator models designed mainly for construction work (with bucket capacities up to 5 cu m) are provided with various interchangeable equipment for earth removal, assembly, hoisting and conveying, loading and unloading, pile-driving and drilling operations, felling timber and uprooting stumps, and so on. They are usually called general-purpose excavators, universal excavators, or convertible shovels, because they are employed in many types of earth-moving and construction work. If the number of interchangeable equipment units is no more than three (for example, a shovel, dragline, and crane), they are known as semiuniversal excavators.

Excavators equipped with a hydraulic drive are widely used; they are suitable for use with all types of operating equipment. The equipment is hinged to a rotating platform and moved by means of hydraulic cylinders driven by high-pressure (10–40 megapascals) pumps. In this case hydraulic motors are usually used to transmit rotation (to turn and move). This type of single-bucket excavator is manufactured with buckets having small (up to 1.8 cu m), medium (2–3 cu m), and large (3.2–6 cu m) capacities; models with bucket capacities of 12–20 cu m are now being put into production in the USSR, primarily equipped with backhoes. The specific power ranges from 133 to 213 kilowatts per cubic meter of bucket, depending on the operating conditions (soft or hard earth).

Single-bucket excavators may be classified according to purpose as construction, open-pit, combination construction and open-pit, and stripping excavators; there are also tunnel, floating, and other types. Construction excavators are the most common single-bucket type (approximately 60 percent worldwide); there are about 200 models produced by more than 80 domestic and foreign factories. They include general-purpose, light-duty excavators with bucket capacities of 0.05–1.8 cu m, crane lifting capacities of 0.7–45 tons, and weights of 1.5–65 tons; semiuniversal, medium-duty excavators with bucket capacities of 2–3 cu m, crane lifting capacities of 60–80 tons, and weights of 72–105 tons; and semiuniversal, heavy-duty excavators with bucket capacities of 3.25–6 cu m, crane lifting capacities of 100–150 tons, and weights of 115–210 tons. The specific weight per cubic meter of bucket capacity for working hard earth is 33–36 tons for such excavators. For the most efficient use, the excavators are equipped with buckets having a capacity of 25–60

percent greater for working soft earth and 20–25 percent smaller for very hard earth. Light-duty machines often have interchangeable crawler and rubber-tire running gear and a single-motor drive. Hydraulic excavators may have individual or composite drives.

Open-pit excavators are usually made with shovel equipment and only rarely with interchangeable dragline and crane equipment. They are notable for the high power of the working equipment, high operating forces and speeds, and a short operating cycle, which are responsible for high output (compared with other excavators of the same size) when used to load hauling units, particularly when working hard earth. Medium-duty excavators with bucket capacities of 2–4 cu m and heavy-duty excavators with capacities of 5–20 cu m and weights of 76–900 tons are designed for open-pit operations, especially with hard rock and earth that have already been blasted, and for loading large dump trucks. They are manufactured both as semiuniversal excavators and as special shovels with standard and extra-long operating eqiupment for overhead loading of hauling units located on the edge of a working face or excavation. They are equipped with crawler running gear and electric power equipment with individual drives for the operating equipment powered by an engine-driven generator. The specific power of the driving engine is 60 to 80 kilowatts per cubic meter of shovel capacity, the pressure exerted on the ground is 0.15–0.25 megapascals, and the speed is 0.6–1.5 km/hr. Hydraulic open-pit excavators have shovel capacities up to 8–9 cu m, and models with capacities of 12–20 cu m are under development.

Combination construction and open-pit excavators of medium and high power are designed mainly for the open-pit mining of nonmetallic building materials. In design they are midway between construction and open-pit excavators.

Stripping excavators are usually equipped with shovels for shifting the stripped earth from open pits to spoil dumps. Those with shovel capacities up to 15 cu m are also used to load hauling units located on the edge of the face. Bucket capacities range from 6 to 153 cu m, and the units weigh from 700 to 12,700 tons. The running gear of heavy-duty models consists of four paired crawler treads. The power equipment is the same as for open-pit excavators. The specific weight ranges from 45 to 90 tons per cubic meter of bucket capacity, and the speed is 0.3–0.5 km/hr. Besides power shovels, stripping operations may also call for the use of walking draglines with booms up to 100 m long, buckets with capacities of 5–168 cu m, and weights up to 14,000 tons. They are the principal equipment used for mining mineral deposits without haulage systems. In 1977 one of the world's largest walking draglines was put into service in the USSR; it has a boom 100 m long and a bucket capacity of 100 cu m.

Tunnel and mine excavators are used underground in excavations having a large cross section to drive tunnels, construct the chambers of underground structures, and excavate minerals. Bucket capacities are from 0.75 to 1 cu m, and weights range from 16 to 30 tons.

Multibucket excavators. Multibucket excavators consist of operating equipment (buckets, an articulated bucket frame, and a boom), a metal superstructure to which the operating equipment is secured, drive mechanisms (power equipment), controls, a platform on which all the subassemblies and units are mounted, and running gear (the lower frame and engine). The running gear may be of the crawler (for any weight), rubber-tire (units up to 30–40 tons), rail, walking, or rail-walking types; the last two are suitable for any weight and for movement over soft earth. During operation, a multibucket excavator digs, scoops, transports, and unloads earth into an arterial conveyor or cars.

Multibucket excavators are divided into two basic categories depending on whether the operating equipment is of the chain or wheel type. In chain excavators with from 12 to 40 buckets, the buckets are attached to an endless chain that moves along rollers in guides on the bucket frame. Most models can provide an accurate final configuration for the banks of excavations and are therefore used in profiling operations (Figures 2,a and 2,b). In wheel excavators the operating member is a wheel having from six to 12 (sometimes up to 24) buckets (Figure 2,d). Earth is emptied out of the wheel buckets directly onto a conveyor located on a rotating boom or through a feeder; it is then transferred to an unloading conveyor. The total distance the earth is transported may be as much as 150 m, the digging height may reach 50 m, and the digging depth may range to 25 m. The wheel is almost completely freed from the task of transporting the earth, so that the excavation rate can be increased to 3–4.4 m/sec instead of the 0.4–1.2 m/sec of chain machines. Light-duty models with buckets having capacities ranging from 25 to 150 liters (*l*) can be used in open pits for excavating nonmetallic building materials; those of medium power with buckets of 200–450 *l* capacity are used for large construction projects; and heavy-duty models with buckets of 500–4,500 *l* capacity are used in large open pits. Wheel excavators are also used for the stockpiling and unloading of large volumes of materials at rates up to 12,500 cu m/hr or more. The excavator weight per liter of bucket capacity ranges from 0.9 to 1.5 tons; the average productivity ranges from 1.8 to 2.5 cu m/hr per liter of bucket capacity.

A distinction is made between multibucket excavators having buckets that move transversely with respect to the movement of the excavator, those with buckets that move longitudinally, and revolving excavators. Transverse excavators (Figure 2) are mainly chain types that move while operating in a direction perpendicular to the plane of motion of the buckets. They are able to excavate overhead and underneath, and they are mounted on rail or crawler running gear. Longitudinal excavators may be chain or wheel types that move while operating in a direction parallel to or

coincident with the plane of motion of the buckets; they thus serve as trenchers. Such machines are usually of low power, with weights up to 75 tons, and are mounted on crawler or rubber-tire running gear. They are designed for digging trenches 0.35–2 m (rarely 3 m) wide with depths from 1.2–2 m (for wheel excavators) to 8 m (for chain excavators). They are also manufactured as units to be mounted on tractors, rubber-tire prime movers, and trucks. Revolving multibucket excavators are of the chain type, with a bucket frame mounted on a rotating platform that turns on a supporting circle; they usually have crawler running gear (Figure 2,c). Provision for 360° rotation increases the weight of an excavator by 30–40 percent. The bucket capacity may reach 3,600 *l*. Such excavators are used to work dummy roads and to excavate two buckets alternately from one horizon by an upper and a lower face.

Multibucket excavators are most productive for concentrated open-pit operations and earthwork in soft, medium, and uniformly hard earth, especially when the transverse contours of the faces are constant or vary little and slopes of the excavation are regular. Light-duty excavators with bucket capacities up to 150 *l* can operate with any type of hauling unit; medium-duty and heavy-duty machines operate with railroad and conveyor haulage.

In addition to stripping operations in open pits, multibucket excavators are used for land reclamation and spoil dumping. In land reclamation, chain machines are usually used to excavate transversely; they are notable for the low specific pressure exerted on the ground (approximately 3×10^4 pascals) and are designed to dig banked trenches and small channels (Figure 2,e). They can excavate to a depth of 2.5 m and dig channels up to 12 m wide. The bucket capacity ranges from 25 to 75 *l*, and the excavators weigh from 12 to 20 tons. The specific power is approximately one kilowatt per liter of bucket capacity, and the productivity ranges from 1.5 to 3 cu m/hr per ton of weight (the higher value applies to the small models). Machines that excavate longitudinally are occasionally used with special equipment. Stripping shovels (Figure 2,f) with wheel or chain operating equipment and a cantilever dumping conveyor are used to handle large-volume spoil-dumping operations when the overburden in open-pit mines is excavated with multibucket excavators. They pile the loose earth of the overburden onto upper spoil banks to a height of 25 m or onto lower spoil banks to a height of 50 m.

History. The idea of creating an earth-moving machine is attributed to Leonardo da Vinci, who proposed a design for a dragline excavator in the early 1500's. The first steam dredger was built at the Izhora Factory under the direction of A. A. Béthencourt in the 1810's, and a single-bucket, nonrevolving excavator was patented in 1835 by W. S. Otis (USA). Single-bucket excavators came into general use in the late 1800's with the expansion of railroad construction. The first electric excavators appeared in 1910, and full-revolving, crawler-mounted excavators with internal-combustion engines appeared in 1912 (with diesel engines in 1916). Full-revolving, medium-power excavators with large operating equipment, mounted on railroad chassis, were first used for open-pit mining in the 1920's. In Russia the production of single-bucket excavators began in 1901 at the Putilov Factory (now the Leningrad Kirov Factory). Excavator production was organized in the USSR in 1931. In 1947 the Urals Heavy Machine-building Plant became the first in the world to begin series production of open-pit excavators with bucket capacities of 3–5 cu m; in 1958 the plant manufactured a walking dragline excavator with a bucket capacity of 25 cu m and a boom 100 m long. In 1965 the Novokramatorskii Machine-building Plant manufactured a power shovel with a 35–cu m bucket for working hard earth. A walking dragline with a bucket capacity of 100 cu m and a boom length of 100 m was fabricated at the Urals Heavy Machine-building Plant in 1975. In 1976 the same plant also readied production for a heavy-duty open-pit power shovel with a bucket capacity of 20 cu m, designed to work hard earth.

The manufacture of excavators abroad is concentrated in the USA (Marion Power Shovel Company, Inc., Bucyrus-Erie Company, and Harnischfeger Corporation), Great Britain, the Federal Republic of Germany, the German Democratic Republic, France, Japan, the Polish People's Republic, the Czechoslovak Socialist Republic, and other countries. In 1968 the Bucyrus-Erie Company fabricated a walking dragline with a bucket capacity of 168 cu m for working soft earth, and the Marion Power Shovel Company manufactured a power shovel with a bucket capacity of 153 cu m.

The multibucket excavator designed for use on land was invented in France by M. Couvreux in 1860 and was used in the construction of the Suez Canal. By the end of the 1800's multibucket excavators were widely used in Germany for the open-pit mining of brown coal. In Russia the production of multibucket excavators was initiated at the Putilov Factory in 1901. In 1921 excavators appeared in Germany with bucket capacities of 525 *l*; in 1933, with capacities of 1,200 *l*; in 1939, with capacities of 1,500 *l*; and in 1941, with capacities of 2,000 *l*. In 1958 a wheel excavator with a bucket capacity of 3,600 *l* was put into operation in the Federal Republic of Germany. In 1967 the Novokramatorskii Machine-building Plant began delivery of high-power wheel excavators with a production capacity of 3,000 cu m/hr, and in 1973, models with a production capacity of 5,000 cu m/hr.

Future development. The principal development trend in the manufacture of excavators is to increase productivity through the use of machines with greater unit power. The makeup of the excavator fleet is changing with the introduction of hydraulic types. The proportion of alloy steels used is being increased to 35–40 percent of the total excavator weight in light-duty excavator designs, 40–50 percent in medium-duty designs, and 70–80 percent in heavy-duty designs. The duration of the operating cycle is being reduced by increasing the speed of the individual operating movements. Rotary excavators are being designed for working rock with a specific excavating resistance up to 16×10^6 pascals. New trenchers with a productivity of 2,500–3,000 cu m/hr are designed to work earth with a specific excavating resistance of 0.8×10^7–1.0×10^7 pascals; they can dig trenches 2–2.5 m wide and as much as 3 m deep at a rate of 400–500 m/hr, which is 10–20 times faster and 5–6 times more economical than existing excavators of the same class are capable of. So-called "baby" excavators weighing 300–800 kg are now widely used. An automatic control system is being developed for continuous-action excavators; it regulates all the parameters that determine the progress of the operating cycle. Systems are being designed on this basis with self-optimizing algorithms for working the foot of banks and entire faces. Automatic control systems are being created to handle all the machines of a continuously operating complex—spoil dumpers, conveyors, and gantries.

EXCITON, a quasiparticle that represents an electronic excitation in a dielectric or a semiconductor. Excitons propagate through a crystal and are not associated with the transfer of electric charge or of mass. The concept of the exciton was introduced in 1931 by Ia. I. Frenkel' (Frenkel), who hypothesized that photoconductivity does not occur in dielectrics upon the absorption of light because the energy absorbed is expended on the formation of excitons rather than the production of charge carriers.

In molecular crystals, an exciton is an elementary excitation of the electron system of an individual molecule. Such elementary excitations are known as Frenkel excitons. Owing to molecular interaction, a Frenkel exciton propagates through a crystal as a wave. Frenkel excitons are manifested in the absorption and emission spectra of molecular crystals (*see* SPECTROSCOPY, CRYSTAL). If a unit cell of such a crystal contains several mole-

cules, molecular interaction results in the splitting of exciton lines. This effect, called Davydov splitting, is associated with the possible transfer of a Frenkel exciton from one group of molecules to another group within the unit cell. Davydov splitting has been observed experimentally in a number of molecular crystals, such as naphthalene, anthracene, and benzene.

In semiconductors, an exciton is a hydrogen-like bound state consisting of a conduction electron and a hole. Such bound states are referred to as Mott-Wannier excitons. The binding energies $\mathcal{E}^*$ and effective radii a^* of Mott-Wannier excitons may be estimated on the basis of N. Bohr's equations for the hydrogen atom if two circumstances are taken into account. First, the effective mass m_e of a conduction electron and the effective mass m_h of a hole differ from the mass m_0 of a free electron. Second, the Coulomb interaction between an electron and a hole in a crystal is reduced by the permittivity ϵ of the medium. Therefore,

$$\mathcal{E}^* = \frac{m^* e^4}{2\epsilon^2 \hbar^2} = \frac{m^*}{m_0 \epsilon^2} \times 13.6 \text{ electron volts (eV)}$$

$$a^* = \frac{\epsilon \hbar^2}{m^* e^2} = \frac{\epsilon m_0}{m^*} \times 5 \times 10^{-9} \text{ cm} \quad (1)$$

where $m^* = (m_e m_h)/(m_e + m_h)$, $\hbar$ is Planck's constant, and e is the charge of the electron.

Equations (1) do not take into account the effect of the complex band structure of a crystal or the interaction of electrons and holes with phonons. However, allowance for these factors does not change the order of magnitude of $\mathcal{E}^*$ and a^*. For Ge, Si, and III-V and II-VI semiconductors, $m^* \sim 0.1\ m_0$ and $\epsilon \sim 10$, yielding $\mathcal{E}^* \sim 10^{-2}$ eV and $a^* \sim 10^{-6}$ cm. Thus, the binding energies of Mott-Wannier excitons are many times lower than the binding energy of the electron and the proton in a hydrogen atom, and the radii of such excitons are many times larger than the interatomic distances in a crystal. The high values of a^* indicate that an exciton in a semiconductor crystal is a macroscopic formation; hence, the crystal structure determines only the parameters m^* and $\mathcal{E}^*$. Therefore, a Mott-Wannier exciton may be regarded as a quasiatom that moves in a vacuum. The distortions of the crystal structure that are caused by a single exciton or by even a large number of excitons are negligibly small. In alkali halide and inert-gas crystals, $\mathcal{E}^* \sim 0.1$–1 eV, $a^* \sim 10^{-7}$–10^{-8} cm, and the formation of an exciton is accompanied by the deformation of a unit cell.

Mott-Wannier excitons are clearly apparent in the absorption spectra of semiconductors as narrow lines that are shifted below the optical absorption edge by a quantity equal to $\mathcal{E}^*$. The hydrogen-like spectrum of such excitons was first observed in the absorption spectrum of Cu_2O and later in other semiconductors. Excitons are also manifested in luminescence spectra, photoconductivity, the Stark effect, and the Zeeman effect. The lifetime of excitons is short; the electron and the hole that constitute an exciton can recombine, emitting a photon. For example, the lifetime of an exciton in Ge is of the order of 10^{-5} sec. An exciton may decay upon colliding with lattice defects.

When excitons interact with photons having frequencies $\omega = \mathcal{E}^*/\hbar$, new quasiparticles called polaritons are formed. Polaritons are mixed exciton-photon states. Their properties, such as their dispersion relation, differ considerably from the properties of both excitons and photons. Polaritons play an important role in the processes by which electronic excitation energy is transferred in a crystal and are responsible for various effects, such as peculiar features in the optical spectra of semiconductors in the exciton-band region.

At low densities, excitons behave in a crystal like a quasiparticle gas. At high densities, the interaction of excitons becomes substantial. For example, a bound state consisting of two excitons may be formed; such a bound state is called an exciton molecule, or a biexciton. However, in contrast to the hydrogen molecule, the dissociation energy of a biexciton is much lower than its binding energy, since the effective masses of electrons and holes in semiconductors are of the same order of magnitude.

If the density of excitons is increased, the distance between the quasiparticles may become of the order of their radius, leading to their collapse. The collapse may be accompanied by the formation of droplets of an electron-hole plasma. The formation of electron-hole droplets in such semiconductors as Ge and Si is manifested in the appearance of a new broad luminescence line that is shifted toward lower photon energies. Electron-hole droplets have a number of interesting properties, including a high concentration of electrons and holes at a low density (averaged over volume) and a high mobility in nonuniform fields.

At low exciton densities, an exciton, which consists of two fermions (a conduction electron and a hole), may be regarded as a boson. Consequently, Bose-Einstein condensation of excitons is possible; that is, a large number of excitons may accumulate in the lowest-lying energy level. Bose-Einstein condensation of excitons may lead to unattenuated energy fluxes in a crystal. However, in contrast to superfluid helium or a superconductor, a superfluid flux of excitons cannot exist for an arbitrarily long time. Such an exciton flux can exist only for the lifetime of the excitons.

EXCITRON, a controlled mercury-arc rectifier (in the Soviet Union, usually multianode) with a cathode spot that, once initiated, is maintained continuously by an excitation anode. Excitrons are used in equipment such as high-power rectifiers. [29–1894–1]

EXCURSION, a visit to some noteworthy place or site, such as a cultural monument, museum, or enterprise; a form and method of acquiring knowledge.

Excursions are generally conducted in groups led by a guide. They may be classified according to purpose as scientific, cultural-educational, and educational excursions; in addition to field trips carried out as part of a vocational guidance program, educational excursions include trips to industrial facilities for learning purposes and trips for the purpose of sharing experience and knowledge with others in one's field of work. Excursions may also be distinguished according to their subject, that is, the nature of the place or sight visited. A third way of classifying excursions is based on whether the object of the excursion is located in its natural setting or is in a museum-like environment. Finally, excursions may be distinguished according to the composition of the excursion group; for example, the members of the group may be of the same age or profession, or they may be tourists or students.

Excursions originated in the late 18th and early 19th centuries as a teaching method for improving students' independent study habits through the development of powers of observation. They were introduced into the educational process by progressive teachers in Western Europe and Russia who were opposed to scholasticism in pedagogy. In the 19th century excursions gradually became an intrinsic part of the educational process for schoolchildren. The Central Excursion Commission was established in Moscow in 1910 to provide excursion services to schoolchildren and teachers. In the same year the book *School Excursions: Their Significance and Organization*, edited by B. E. Raikov and G. N. Boch, was published; it dealt with the basic methodology of excursions.

Cultural-educational excursions developed alongside educational excursions in the late 19th and early 20th centuries, and special excursion organizations were established. The organization Excursions Through Russia was founded in 1907 as part of the Russian Society of Tourists. The magazine *Ekskursionnyi vestnik* was published in Moscow from 1914 to 1916, and the magazine *Russkii ekskursant* in Yaroslavl from 1914 to 1917.

The Soviet government's first decrees on schools treated excursions as a necessary element in the educational process. The Central Bureau of School Excursions was established in Moscow in 1918. In the late 1920's and early 1930's cultural-educational ex-

cursions became a component of tourism. The joint-stock company Soviet Tourist was founded in 1928 and was reorganized in 1930 as the All-Union Voluntary Society for Proletarian Tourism and Excursions. In the 1930's excursion tour stations of the People's Commissariat for Education were opened in several cities, including, in 1932, the Central Station in Moscow. In 1936 the Central Executive Committee of the USSR entrusted the All-Union Central Council of Trade Unions (VTsSPS) and its member organizations with the development of tourism and excursions.

After the Great Patriotic War of 1941–45 there was an increase in the activities of the tourist and excursion institutions and organizations of the VTsSPS in all Union and autonomous republics, krais, and oblasts. In large cities tourism councils were established that consisted of representatives of state and public organizations providing tourist and excursion services for working people. A new stage in the development of excursions was inaugurated in 1969 by the decree of the Central Committee of the CPSU, the Council of Ministers of the USSR, and the VTsSPS On Measures for the Further Development of National Tourism and Excursions. The number of excursionists increased from 35 million in 1970 to 152 million in 1977. In this period excursion organizations were opened in 600 cities; they offered a total of more than 15,500 excursions in such fields as industry, history, natural history, architecture, art, and literature.

According to an estimate made in 1977, the average annual number of guides employed by the trade unions' system of excursion services is approximately 35,000. In 1977 there were 1,200 museums, art galleries, and exhibitions providing scientific, cultural, and educational excursion services on a large scale; they were visited by approximately 120 million people a year. The Central Lenin Museum in Moscow and its branches enjoy the greatest popularity, with more than 6 million visitors each year.

The USSR has a high index of excursion participation, that is, a high number of visits to excursion sites per capita; in 1975 there were more than 1,200 visits per 1,000 members of the population. Specialized excursion services for schoolchildren are offered by the Children's Excursion Tour Stations of the Ministry of Education of the USSR; in 1977 there were more than 200 such stations, and about 8 million schoolchildren took part in excursions. Soviet schools make wide use of excursions in the educational process. The schools provide subject excursions, or excursions related to subjects in the curriculum; industrial excursions, which V. I. Lenin regarded as one of the ways to solve problems of general and polytechnic education; combined excursions, which combine different subjects of study; and cultural-educational excursions.

The excursion method is used in programs for the vocational guidance of youth, in systems for improving the skills of workers and exchanging experience and knowledge concerning new techniques and methods of work, and in the production of educational films and television programs.

In the developed countries, excursions have become an integral part of traveling and one of the purposes of travel, and excursion tourism has been developed as a means of learning about the world. The excursion as a recreational activity is of great social value, since it fulfills several functions at the same time: it facilitates interpersonal contact, the acquisition of knowledge, and improvement of health. The necessity of providing services for excursionists on a mass scale has led to the appearance of specialized institutions, such as excursion bureaus; specialized workers, such as guides and methodologists; and specialized means of transportation, including modifications of buses and riverboats.

EXECUTIVE COMMITTEE RANGE, a section of a massif on Marie Byrd Land in Western Antarctica. The range extends from 76°20′ to 77°20′ S lat. It is composed of basalts. Individual mountain peaks rise above the ice sheet, which has a thickness of approximately 1,000 m in the region; the range reaches a maximum elevation of 4,181 m at Mount Sidley. Executive Committee Range was discovered in 1940 by an American expedition under the leadership of R. Byrd. It was named in honor of the Executive Committee of the Antarctic Service of the USA. [29–1674–2]

EXEKIAS. Greek potter and vase painter of the third quarter of the sixth century B.C. Exekias was the most outstanding representative of the late black figure style. His works include painted amphorae, for example, *Achilles in Battle With Penthesilea and Memnon With a Negro* and *Hercules Fighting the Nemean Lion* (both housed in the Antiquities Collection, Berlin), as well as *Ajax With the Body of Achilles* (Glyptothek, Munich). He also made kylikes, including the Nike kylix (Louvre, Paris) and *Dionysos Crossing the Sea* (Glyptothek, Munich). [29–1891–4]

EXEQUATUR, in international law:

(1) An authorization for a consular officer to perform his functions in his consular district in the state to which he is accredited. The exequatur is issued by the competent bodies of the country of destination when the officer presents his consular commission; it is issued in the form of a special document or sometimes a special notation made on the commission. In accordance with Soviet legislation, exequaturs are issued by the Ministry of Foreign Affairs of the USSR.

(2) An authorization for the compulsory execution in a given country of a judgment pronounced by a court in another country. The exequatur takes the form of a legal order by which a court acknowledges the legal force of a foreign court's decision and extends the effect of the ruling to the territory of its own state. This type of exequatur is usually implemented by appellate courts.

Soviet legislation permits the recognition and execution of foreign court and arbitration judgments that are legally valid, do not conflict with Soviet sovereignty, and do not threaten the security of the USSR. It is required, however, that the USSR have concluded an appropriate agreement with the corresponding government or that the given legal area be governed by an international convention. The judgments must be presented to the Soviet court within three years from the time they are pronounced.

Exequaturs are not used in international legal relations between socialist countries. When necessary, decisions of foreign courts are carried out on the basis of agreements of legal assistance. [29–1753–7]

EXERCICE, a group of practice exercises in ballet that helps dancers develop muscles and ligaments and that promotes coordination of movements. The practice exercises are performed at the *barre* (a bar attached to a wall with brackets) and in the center. The daily *exercice* consists of the same elements. [29–1755–2]

EXERGY, a term used in thermodynamics to designate the maximum work a system can perform on moving from a given state to equilibrium with its surroundings. The work done by a system in a particular thermodynamic process is maximal only if the process is an equilibrium process. [29–1891–5]

EXETER, a city and borough in southwestern England. Port on the River Exe. Seat of Devon County. Population, 93,300 (1976). Exeter has enterprises of the machine-building and food-processing industries. The city has a university.

Exeter is located on the site of a Celtic settlement. Traces of regular Roman street layout remain; however, the historical part of the city, located within the standing portions of a wall dating to the Middle Ages, presents a picture of unplanned growth. Structures of architectural interest include the ruins of the late Romanesque castle on Rougemont Hill (begun 1068), a 12th-century guildhall combining the Romanesque and Gothic styles (rebuilt

14th and 16th centuries), and a Gothic cathedral in the decorated style (originally a Romanesque church; rebuilt 1275–1375). The Royal Albert Memorial Museum, with archaeological collections of pottery and bronzes, is located in Exeter.

REFERENCE

EXHAUSTER, an obsolete name for a fan, usually a centrifugal fan, that creates a suction and is designed to remove dust, flue gases, and other harmful impurities from the air of production areas. Exhausters are also used in pneumatic conveying systems for the removal of the waste materials generated in certain industrial processes. [29–1890–5]

EXHUMATION, the removal of a corpse from a burial site. According to Soviet law, a body may be exhumed at the request of an investigator, who must state the purpose of doing so: an investigatory view (or a second investigatory view) of the body, identification of the deceased by an acquaintance or an expert, or presentation of the body for primary, additional, or follow-up forensic expertise (medical, biological, or toxicological). The most frequent reason for exhumation is to examine a body that should have been subjected to forensic medical expertise owing to the circumstances of death but that was buried without an autopsy.

Witnesses, a forensic medical expert, and, if necessary, another specialist, such as a health inspector, are present at an exhumation. The investigator prepares a protocol of the exhumation, which includes photographs of the grave, gravestone, coffin, and corpse. [29–1891–2]

EXINE (also exosporium), in seed plants, the outer layer of the wall of pollen grains (microspores). In many plants the outside of the exine has nodules or reticular enlargements, which form specific patterns characteristic of a particular species and are therefore often used to identify the species to which a pollen grain belongs. [29–1755–4]

EXISTENTIALISM, or existential philosophy, an irrationalist current in contemporary bourgeois philosophy that emerged on the eve of World War I in Russia (L. Shestov and N. A. Berdiaev), after World War I in Germany (M. Heidegger, K. Jaspers, and M. Buber), and during World War II in France (J.-P. Sartre, G. Marcel, M. Merleau-Ponty, A. Camus, and S. de Beauvoir). Existentialism gained further currency throughout Europe during the 1940's and 1950's, and in the USA during the 1960's.

In Italy, the best-known existential thinkers are E. Castelli, N. Abbagnano, and E. Paci; in Spain, J. Ortega y Gasset was close to existentialism; and in the USA, the existential philosophy was popularized by W. Lowrie, W. Barrett, and J. Edie. Certain religious-philosophical currents are closely related to existentialism—specifically, French personalism, as represented by E. Mounier, M. Nédoncelle, and J. Lacroix, and the dialectical theology of K. Barth, P. Tillich, and R. Bultmann. B. Pascal, S. Kierkegaard, M. de Unamuno, F. M. Dostoevsky, and F. Nietzsche are regarded as the precursors of existentialism by its adherents. The philosophy of life and the phenomenology of E. Husserl were influential in the development of existentialism.

Diverging from traditional rationalist philosophy and science, in which mediation is considered the basic principle of thought, existentialism seeks to comprehend being as a kind of unmediated and undivided unity of subject and object. Primordial and authentic being is identified with experience, which is interpreted in existentialism as the subjective experience of "being-in-the-world." The existentialist regards being as an unmediated given, or as human existence—which, in his judgment, cannot be known by scientific or even by philosophical means.

In order to describe the structure of existence, many of the existentialists, such as Heidegger, Sartre, and Merleau-Ponty, resort to the phenomenological method of Husserl; they consider the structure of consciousness to be constituted of its orientation toward the other—that is, its intentionality. Existence is "open"; it is directed toward the other, which becomes its center of attraction. According to Heidegger and Sartre, existence is being, which is directed toward nothing and is aware of its own finiteness. Thus, Heidegger's description of the structure of existence amounts to a description of the various modes of human existence—such as concern, dread, resolution, and conscience—which are defined by death and which represent various means of contact with nothingness, movement toward or flight from nothingness, or other type of relation to it. Thus, too, it is at moments of extreme shock, which Jaspers calls boundary situations, that existence reveals itself to man as the root of his being.

Existentialism defines existence by its finiteness; the latter is interpreted as temporality, whose reference point is represented by death. In contrast to physical time, which is pure quantity, or an endless series of passing moments, existential time is qualitative, finite, and nonrepeatable; for Heidegger and Jaspers, it represents fate. Existential time is inseparable from that which constitutes the essence of existence, including birth, love, repentance, and death. What the existentialists emphasize in the phenomenon of time is the decisive significance of the future; viewing the future in conjunction with such existential concepts as "resolution," "project," and "hope," they stress the personal-historical (rather than the impersonal-cosmic) nature of time and affirm its connection to human activity and to men's strivings, efforts, and expectations.

In existentialism, the historicity of human existence is reflected in its always being in a given situation—a situation into which it is "thrown" and with which it is forced to reckon. The individual's membership in a particular nation or caste and his being endowed with such specific qualities as biological and psychological traits—all these circumstances are empirical manifestations of the fundamentally situational nature of existence, or of its "being-in-the-world." The temporality, historicity, and situational nature of existence are modes of its finiteness.

Another important existential concept is transcendence, or "being beyond." The different types of philosophical reasoning that distinguish the various exponents of existentialism depend on the particular interpretation of the transcendent and of the very act of transcending. Jaspers, Marcel, and the late Heidegger acknowledge the reality of the transcendent; the predominant element in their philosophy is the symbolic, or even (in Heidegger) the mythic-poetic—in that the transcendent is unknowable and can only be "alluded to." This may be contrasted to the critical doctrine of Sartre and Camus, who set themselves the goal of demonstrating the illusory nature of transcendence.

Existentialism rejects both the rationalist tradition of the Enlightenment, which reduces freedom to the recognition of necessity, and the humanist-naturalist tradition, for which freedom consists in discovering man's natural inclinations and liberating his "essential" forces. For the existentialist, freedom is existence itself, and existence is freedom. Inasmuch as the structure of existence is expressed in "movement-toward" (that is, movement toward something that is not one's own existence), or transcendence, the existentialist's definition of freedom depends on his interpretation of transcendence. For Marcel and Jaspers, this means that freedom can be found in god alone. For Sartre, on the other hand, inasmuch as to be free means to be oneself, "man is doomed to be free." In existentialism, freedom represents a heavy burden; man, insofar as he is an individual being, must bear that burden. He can renounce his freedom, can cease being himself, and can become "like all," but only at the cost of repudiating himself as a person.

For Heidegger, the world in which man is immersed is called "they" (in German, *man*); it is an impersonal world where everything is anonymous, where there are no subjects of actions but only objects of actions, and where everyone, including man in relation to himself, is "other"; it is a world in which no one decides anything and therefore no one is responsible for anything. For Berdiaev, this world is called "the world of objectification," and its attributes are "(1) the alienation of the object from the subject; (2) the absorption of the uniquely individual and personal by the general, impersonal, and universal; (3) the dominant role of necessity and of determinability from without, entailing the suppression and shutting out of freedom; and (4) the adjustment to the massive scale of the world and history, accommodation to

the average man, and socialization of man and of man's opinions, resulting in the destruction of originality" (*Opyt eskhatologicheskoi metafisiki*, Paris, 1949, p. 63).

Contacts between individuals in this objectified world are not genuine; they merely underscore each person's isolation. According to Camus, we are confronted with nothingness, which makes human life senseless and absurd; the gap between individuals cannot be bridged, and genuine intercourse between them is impossible. Both Sartre and Camus see falsity and hypocrisy in all forms of personal intercourse—such as love and friendship—sanctified by traditional religion and morality. Sartre's characteristic passion for exposing distorted and transmuted forms of consciousness, or "bad faith," turns in essence into the demand for acceptance of the reality of consciousness as detached from others and from itself. Camus acknowledges only one mode of genuine intercourse—namely, the unity of individuals in revolt against the "absurd" world and against the finiteness, mortality, imperfection, and senselessness of human existence. Ecstasy may unite one individual with another, but in essence this is the ecstasy of destruction, or rebellion, engendered in "absurd" man by despair.

Marcel proposes a different solution to the problem of human intercourse. In his view, the disconnectedness of individuals is due to the fact that the being of objects is taken to be the only possible being. But genuine being, or transcendence, is not the being of objects; rather, it is personal being, and consequently the authentic relationship to being is dialogue. Being, according to Marcel, is not "it" but "thou"; therefore the prototype of man's relation to being is his relation to another person, as witnessed by god. Transcendence is the act by means of which man goes beyond the limits of his locked-in egoistic self. Love is transcendence—breaking through to the other, be the other human or divine; insofar as this breakthrough cannot be understood by means of reason, Marcel assigns it to the sphere of "mystery."

Genuine human intercourse is not the only way of breaking through the objectified world, or the world of the "they"; according to the existentialists, such breakthroughs also take place in the sphere of artistic and philosophical creativity. Both genuine communication and creativity, however, carry within themselves a tragic flaw: the world of objectivity constantly threatens to destroy existential communication. For this reason, according to Jaspers, everything in the world is ultimately subject to destruction by virtue of the very finiteness of existence, and man must therefore learn to live and love with the constant awareness that everything he loves is fragile and finite, not excluding love itself. But the deeply hidden pain resulting from such awareness imparts a particular purity and spirituality to man's affections. Berdiaev's eschatological doctrine is based on this awareness of the fragility of any form of authentic existence.

The predominant mood in existentialism is one of dissatisfaction and searching; the existentialist seeks to negate and go beyond what has been attained. The tragic and generally pessimistic slant of this philosophy testifies to the state of crisis of contemporary bourgeois society and the extreme forms of alienation prevailing therein; existentialism may therefore be called the philosophy of crisis.

The various exponents of existentialism differ in their sociopolitical positions. Thus, Sartre and Camus were members of the resistance movement; beginning in the late 1960's, Sartre's position was marked by extreme left radicalism and extremism. Camus's and Sartre's ideas were particularly influential in shaping the sociopolitical program of the new left movement. Jaspers and Marcel were liberals in their political orientation, while the sociopolitical views of Heidegger—in his time a Nazi collaborator—are markedly conservative in nature.

Existentialism reflected the spiritual state of bourgeois society and laid bare its ills and contradictions; it was unable, however, to propose a way out of the situation.

The ideas and themes of existentialism have been treated in Western European, American, and Japanese contemporary literature; their influence can be traced not only in the literary works of the existentialist philosophers themselves—Sartre, Camus, Marcel, and de Beauvoir—but also in the work of such writers as A. Malraux, J. Anouilh, E. Hemingway, N. Mailer, J. Baldwin, I. Murdoch, W. Golding, and Abe Kobo.

P. P. GAIDENKO [29–1755–5]

EXKUSEIA, a form of privilege in Byzantium between the tenth and 15th centuries.

Exkuseia released the owner of privileged landholdings and the peasants living on them from state taxes (usually extraordinary taxes) and removed the lands from the jurisdiction of state officials, such as tax collectors, theme judges, and military officials. In Byzantium oppressive taxes were the most important means of exploiting the rural population, and *exkuseia* created a type of landowning with special privileges; the state, however, retained supreme jurisdiction over the property and could limit or withdraw the privilege. From the 13th to 15th centuries, those people to whom *exkuseia* had been granted had the right to collect legal duties.

Exkuseia could take other forms as well, such as releasing the recipients of the privilege from taxes on the condition that they perform certain tasks; imperial gunsmiths and state postal workers received this type of privilege. Another form of *exkuseia* released ships from the payment of trade duties.

Many Byzantine scholars—including the Russian researchers K. N. Uspenskii and P. A. Iakovenko and the Yugoslav historian G. Ostrogorskii (Ostrogorski)—regard *exkuseia* as identical to the Western European institution of immunity. The two institutions certainly fulfilled the same social function—the development of privileged landowning.

EXOBIOLOGY, an experimental scientific discipline concerned with the search for and investigation of extraterrestrial life forms. Exobiology is primarily interested in the determination of the limits of the study of the mechanisms of survival of terrestrial organisms under extreme environmental conditions, the elucidation of pathways of abiogenic synthesis of the most important bio-organic compounds and the stages of prebiological evolution, and the establishment of criteria for the existence and development of automated methods of discovering life on other planets by means of automated biological laboratories.

It has been established that many terrestrial microorganisms or their spores can retain their viability at low temperatures (below −70°C), in a vacuum (as low as 10^{-7} to 10^{-10} mm Hg), and at low air humidities (1–2 percent). The abiogenic synthesis of amino acids, lipids, nucleotides, sugars, and other biologically important substances has been effected by the action of ultraviolet rays on simple compounds, such as water, ammonia, carbon

monoxide, and methane. This has made it possible to advance the concept in exobiology of the possibility of life on other planets, first and foremost on Mars, which is constructed on a carbon-organic aqueous base. In the search for extraterrestrial life, exobiology uses various methods and devices to identify complex organic compounds, including gas chromatography, mass spectrometry, and optical instruments that record the absorption spectra and luminescence of substances from extraterrestrial soils. Functional methods are used to determine active metabolism by recording parameters of growth, reproduction, and gas exchange of microorganisms during incubation of soil specimens on combined nutrient media of complex composition. Only the combined use of various methods according to a single program in the automated biological laboratory can eventually bring success.

In 1976 the space probe Viking (USA), with an automated laboratory on board, successfully landed on Mars. However, the first exobiological experiment on Mars provided no evidence of life on the planet. Further experiments may be carried out both by means of automated biological laboratories and by the direct study of soil samples brought from Mars to the earth. Similar investigations carried out on lunar soil specimens indicate the absence of life on the moon in the past and present.

EXOCRINE GLAND, in animals and humans, a gland that secretes the substances it forms through ducts onto the surface of the body or of mucous membranes or into a cavity. Exocrine glands include the sebaceous, salivary, sweat, mammary, lacrimal, and musk glands, as well as the liver, glands of the gastrointestinal tract, and other glands that release secretions into the alimentary canal. [29–1761–6]

EXOGAMY, the practice of marrying only outside one's own group, as prescribed by law or custom in the age of the primitive communal system. The ban could apply to marriages within one's family group (such as the clan or phratry) or, more rarely, to marriages within one's regional group or community. The prohibition against such marriages was retained in later times.

There are numerous theories concerning the origin of exogamy; the theories basically fall into three groups. Some researchers, including L. H. Morgan, believe the practice arose from the need to avoid the possibly harmful consequences of marriages between blood relatives. Others, including E. Tylor, A. M. Zolotarev, and C. Levi-Strauss, regard it as an attempt to expand social contacts and initiate relations with other groups. Still others, including S. P. Tolstov and Iu. I. Semenov, regard it as a means of establishing social peace within a group, since sexual relations and the conflicts that accompany them are thus carried beyond the confines of the group.

EXOGASTRULATION, an experimentally induced disturbance of the process of gastrulation in animal embryos, effected, for example, by the removal of the egg membranes or a change in the pH of the medium. Exogastrulation consists in a change in the direction of morphogenetic movements of cells and cell layers of the embryo. In amphibians, for example, the material of the chordomesoderm and the endoderm, which normally goes inside the embryo, moves to the outside and has no contact with the exoderm over almost its entire surface. In the subsequent development of the exogastrulated embryo, the nervous tissue in the ectoderm does not become differentiated. An atypical epidermis is formed, while the material of the chordomesoderm and the entoderm undergoes differentiation.

Exogastrulation demonstrates the necessity of contact between the chordomesoderm and the ectoderm for induction of the rudiment of the nervous system. It also shows that various morphogenetic movements must be coordinated for the normal course of gastrulation. [29–1760–1]

EXOGENOUS, in botany, a term referring to the development of lateral organs in the peripheral cell layers of the main axis of a particular plant organ. Examples of exogenous organs are the leaves that develop in the form of external nodes on the growing point of shoots, root hairs (which are lateral growths of root integuments), and some epidermal growths (trichotomes) of a plant's aboveground organs. [29–1761–2]

EXOGENOUS NUTRITION, the process whereby substances entering the body from the environment are assimilated. Ingested food is broken down into comparatively simple chemical compounds, which are absorbed and then used to build tissues and organs and to regulate functions. The chemical compounds provide the energy needed for life processes. [29–1760–2]

EXOGENOUS PROCESS, a geological process caused by sources of energy exterior to the earth's surface, chiefly solar radiation, in combination with the force of gravity.

Exogenous processes occur at or near the surface of the earth's crust and are the mechanical and physicochemical interactions of the crust with the hydrosphere and atmosphere. They include weathering and the geological action of wind (eolian processes, deflation), flowing surface and groundwaters (erosion, denudation), lakes and swamps, the waters of the seas and oceans (abrasion), and glaciers (exaration). The most important manifestations of exogenous processes on the earth's surface are the disintegration of rocks and chemical transformation of their constituent minerals (physical, chemical, and organic weathering), the removal and transport of the resulting loosened and soluble products by water, wind, and glaciers, and the deposition (accumulation) of these products in the form of sediments on land or at the bottom of water basins and their gradual transformation into sedimentary rocks (sedimentogenesis, diagenesis, catagenesis).

Exogenous processes, together with endogenous processes, contribute to the shaping of the earth's relief and the formation of sedimentary rocks and associated ore deposits. Thus, for example, ores of aluminum (bauxites), iron, nickel, and other minerals form under conditions of weathering and sedimentation. The selective deposition of minerals by flowing waters results in the formation of gold and diamond placers. Combustible minerals form under conditions favorable to the accumulation of organic matter and sedimentary strata rich in such matter.

EXOPEPTIDASE, an enzyme of the hydrolase class. Exopeptidases catalyze the splitting of amino acid residues from an amine or carboxyl end of a protein or peptide molecule. The two main kinds are aminopeptidases and carboxypeptidases. [29–1762–1]

EXOPHTHALMOS, protrusion of the eyeball. Exophthalmos is most commonly caused by diffuse toxic goiter. It may also be caused by a tumor in the eyeball or adjacent regions, trauma of the eyeball, thrombosis of the orbital veins, and inflammatory diseases. If pronounced, exophthalmos may be accompanied by limited mobility of the eyeball and impairment of vision. Therapy is based on the cause of the condition. [29–1763–4]

EXOSOMATIC ORGAN (also ectosomatic organ), a concept introduced into animal morphology by the Soviet zoologist A. N. Severtsov to designate organs whose functions are directly linked with the external (in relation to the living organism) environment. Exosomatic organs include the skin and its appendages

(feathers, hairs, scales), sense organs, and the intestinal canal and its glands.

EXOSPHERE, the outer and most rarefied layer of the atmosphere, where the mean free path of the particles is so large that they can be dispersed (diffused) into interplanetary space. The mass of the "air" in the exosphere is close to 10^{-10} times the mass of the atmosphere. Light gases, such as H and He, are the most quickly dispersed.

The exosphere begins at altitudes of 450 to 800 km, and its upper boundary is several thousand km above the earth's surface, where the concentration of particles is the same as in interplanetary space. The exosphere consists of ionized gases (plasma), and the ratio of charged particles to neutral particles is close to unity where it begins; in the upper half of the exosphere, the air is almost completely ionized. The lower and middle parts of the exosphere are composed mainly of O and N atoms; with increasing altitude, the relative concentration of light gases, especially ionized hydrogen, grows rapidly. The gas kinetic temperature of the exosphere, which increases somewhat with altitude, is 1500° to 3000° K. An increase in solar activity warms the exosphere and increases its thickness. The magnetic field of the earth, which has an intensity of 0.3 oersted in the lower part of the exosphere and 10^{-2} to 10^{-3} oersted at its upper boundary, strongly affects the physical processes within it. The radiation belts of the earth are located for the most part in the exosphere.

EXOSTOSIS, a benign bony or bony-cartilaginous growth on the surface of a bone in the form of a linear or round mass. Exostoses develop mainly in males during childhood and adolescence, on the femur, tibia, humerus, and other bones. They cease to enlarge when bone growth ends. They usually do not cause complaints. However, fairly large exostoses compress muscles and nerve trunks, causing pain and hampering movement. The principal means of diagnosing exostoses is by X ray.

Exostoses are removed surgically if symptoms are pronounced or if the exostoses suddenly begin to grow rapidly in adults. Individuals suffering from exostoses are kept under clinical observation. [29–1762–4]

EXOTHERMIC REACTION, a chemical reaction in which heat is given off. Examples of exothermic reactions are combustion, neutralization, and most of the reactions involving the formation of chemical compounds from elements. The amount of heat liberated during an exothermic reaction depends on the type of reaction, the mass and nature of the reagents, the phase of the products and reactants, and the specific conditions under which the reaction occurs (for instance, temperature and pressure). The heat of reaction of an exothermic reaction is equal in absolute value but opposite in sign to that of the corresponding endothermic reaction. [29–1763–1]

EXTENDED-DAY SCHOOLS AND GROUPS, general-education schools, or groups within such schools, in which students spend the entire day (ten hours).

Extended-day schools first appeared in 1919 in Petrograd and other large cities of the USSR to increase the pedagogical supervision of children; owing to economic constraints, however, they did not undergo further development. After the Great Patriotic War of 1941–45, separate extended-day groups were established at general-education schools to give families more help in raising their children. The groups were given legal status in 1956 (for Moscow and Leningrad, 1955).

In the period since 1962, as eight-year education has become nearly universal and the system of universal secondary education has been implemented, extended-day schools have been established, at which at least 80 percent of the students must be on the extended-day program. Where the percentage is less, students are enrolled for an extended day in extended-day groups at conventional general-education schools.

Extended-day schools and groups offer a wide range of activities beyond the usual classes; children engage in Pioneer and Komsomol activities, socially useful work, games, sports, and independent projects. The extended-day program may comprise separate grades, or it may involve groups made up of students from various grades. In accordance with sound medical and pedagogical practice, the children study, work, and rest in turn; as part of the program they prepare their homework while at school. The children leave for home when their parents return from work. In some cases, parents are completely or partially released from the requirement of paying for the three meals a day their children receive at extended-day schools or groups.

EXTRAORDINARY ALL-RUSSIAN CONGRESS OF SOVIETS OF PEASANTS' DEPUTIES, a congress held from Nov. 11 (24) to Nov. 25 (Dec. 8), 1917, in Petrograd. The first session was attended by approximately 260 voting delegates. The session of November 18 (December 1) was attended by 330 delegates, among whom were 195 Left Socialist Revolutionaries (Left SR's), 37 Bolsheviks, and 65 right-wing Socialist Revolutionaries and centrists. The number of delegates increased at subsequent sessions. Delegates from provincial, district, and *volost* (small rural district) soviets of peasants' deputies and from front, army, corps, and division peasant committees were present at the congress. Points on the agenda included the agrarian question, the food-supply problem, and the consolidation of Soviet power.

On all major issues the congress supported the positions of the Second All-Russian Congress of Workers' and Soldiers' Deputies, held from October 25 (November 7) to October 27 (November 9) of the same year. After approving the policies of the Council of People's Commissars, the delegates voted their support for the participation of the Left SR's in the Soviet government. Taking the floor three times (twice on the agrarian question), V. I. Lenin stressed that an accord with the Left SR's was possible only within the framework of a socialist platform. On the agrarian question the congress adopted the Left SR resolution, which called for leveling of land tenure.

The goals of the socialist revolution required the amalgamation of soviets of workers', soldiers', and peasants' deputies. The congress adopted a resolution approving the convocation of the Second All-Russian Congress of Soviets of Peasants' Deputies, which was held from November 26 (December 9) to December 10 (23). As a result, the provisional Executive Committee of the soviets of peasants' deputies, elected by the extraordinary congress, merged with the All-Russian Central Executive Committee. On November 15 (28), a joint session of the All-Russian Central Executive Committee, the Petrograd Soviet of Workers' and Soldiers' Deputies, and the Extraordinary All-Russian Congress of Soviets of Peasants' Deputies was held in the Smol'nyi. The session approved the decrees of the Second All-Russian Congress of Soviets on peace and on land and the All-Russian Central Executive Committee's decree of Nov. 14 (27), 1917, on workers' control.

EXTRAORDINARY AND INCREASED SECURITY (Russian, *chrezvychainaia i usilennaia okhrana*), a set of measures used by the tsarist government in its struggle against the revolutionary and social movement in Russia between 1881 and 1917. The measures were introduced during the revolutionary situation of the late 1870's and early 1880's by the Statute on Measures for the Protection of State Order and Public Tranquility of Aug. 14, 1881.

A state of increased security could be introduced by governors-general or by the minister of the interior for a period of one year in localities where public tranquility had been disturbed by "offenses against the existing state order." The administrative authorities of such localities were given the right to disband assemblies, exile suspicious individuals, transfer criminal cases to military courts, and conduct searches.

In localities where the population had been "brought into a state of alarm," the Committee of Ministers (from 1906, the Council of Ministers) could proclaim a state of extraordinary security for a period of six months, thereby giving the governors-general the additional right to dismiss elected or appointed officials, suspend the publication of periodicals, close educational institutions, and create special paramilitary squads for the suppression of disorders.

The extraordinary and increased security introduced as a temporary measure in 1881 was maintained until February 1917.

EXTRAORDINARY BUDGET (Russian, *chrezvychainyi biudzhet*), part of the state budget in Russia in the late 19th and early 20th centuries. From 1894 the state budget of tsarist Russia comprised an ordinary budget and an extraordinary budget. The revenues of the latter were made up of receipts from the sale of government property and loan payments by railroad companies. Disbursements from the extraordinary budget went toward railroad construction and equipment and toward expenditures necessitated by natural disasters, wars, and the prepayment of loans. The extraordinary budget was abolished in May 1919. [29–692–1]

EXTRAORDINARY EIGHTH CONGRESS OF SOVIETS OF THE USSR, a congress held in Moscow from Nov. 25 to Dec. 5, 1936. The congress was attended by 2,016 voting delegates, 42 percent of whom were industrial workers, 40 percent, peasants, and 18 percent, nonindustrial workers. Communist Party members made up 72 percent of the delegates, and 63 nationalities were represented.

The congress was convened to consider and ratify a draft of the new constitution of the USSR. The draft was submitted by the Constitutional Commission of the Central Executive Committee of the USSR, which had been elected on Feb. 6, 1935, on the basis of a resolution of the Seventh Congress of Soviets of the USSR. After being approved by the Presidium of the Central Executive Committee of the USSR on June 11, 1936, the draft had been published for national discussion, which had lasted five months.

In a report given at the congress, J. V. Stalin presented an analysis of the radical changes that had occurred in the sociopolitical life of the country between 1924, when the first constitution of the USSR was adopted, and 1936. He declared that the complete dominance of the socialist economic system had been established (by 1937 the instruments and means of production under socialist ownership constituted 98 percent of the country's production assets). The exploitation of man by man had been eliminated, he asserted, since massive collectivization had done away with the kulaks, the last remaining exploiting class. Thus, the class structure of society had changed. Moreover, the social nature of the working class, of the peasantry, and of the intelligentsia had taken a new form, and sociopolitical and ideological unity of the Soviet people had been achieved. Stalin asserted that the strengthened friendship among the peoples of the USSR signified the unquestionable victory of the Leninist nationalities policy. All of these changes were reflected in the draft of the new constitution.

After approving and adopting the draft as the basis for a final text, the congress set up the Editorial Commission, which consisted of 220 members and was chaired by Stalin. The Commission was formed to study the corrections and additions that had been introduced both in the course of the national discussion and at the congress itself. On Dec. 5, 1936, the congress unanimously ratified the final text submitted by the Editorial Commission. The constitution remained in effect until a new one was adopted in 1977.

EXTRAORDINARY FOURTH ALL-RUSSIAN CONGRESS OF SOVIETS OF WORKERS', PEASANTS', SOLDIERS', AND COSSACKS' DEPUTIES, a congress held from Mar. 14 to Mar. 16, 1918, in Moscow. The congress was attended by 1,232 voting delegates, among whom were 795 Bolsheviks, 284 Left Socialist Revolutionaries (Left SR's), and 21 Mensheviks. The agenda included ratification of the Brest-Litovsk Treaty, on which V. I. Lenin presented a report and B. D. Kamkov, a member of the Left SR faction, delivered an additional report; relocation of the seat of government; and the election of the All-Russian Central Executive Committee.

After G. V. Chicherin apprised the congress of the peace treaty signed with Germany in Brest-Litovsk on March 3, Lenin took the floor to explain that ratification of the treaty was the only way to secure the respite needed to preserve and consolidate the achievements of the October Revolution. A continuation of the war with German imperialism threatened destruction of Soviet power. Representatives of the petit bourgeois parties—Kamkov, the Menshevik L. Martov, the communist anarchist A. Iu. Ge, and the SR Maximalist N. I. Ryvkin—opposed ratification. In a roll-call vote after Lenin's and Kamkov's final speeches, 784 delegates voted for ratification of the treaty, 261 voted against it, 84 delegates did not vote for various reasons, and the rest, including Left Communists, abstained. After the vote, the Left SR's announced their withdrawal from the Council of People's Commissars.

After ratifying the treaty, the congress affirmed the need "to spare no efforts in restoring and increasing the defense capability of our country" and declared itself in favor of Soviet assistance to the international socialist movement. The Ukrainian Central Executive Committee of Soviets and delegates from Soviet organizations of the Ukraine issued a declaration approving the ratification of the treaty. The congress ratified the decision adopted by the All-Russian Central Executive Committee in late February 1918 to move the seat of government of the Soviet republic from Petrograd to Moscow. A new All-Russian Central Executive Committee consisting of 207 members was elected.

EXTRAORDINARY SEVENTEENTH ALL-RUSSIAN CONGRESS OF SOVIETS, a congress held in Moscow from Jan. 15 to Jan. 21, 1937. The congress was attended by 1,338 delegates and represented 43 nationalities. Industrial workers made up 47.6 percent of the delegates, peasants, 16 percent, and nonindustrial workers, 36.4 percent.

The congress was convened to consider and ratify the new constitution of the RSFSR; the draft of the constitution had been drawn up in accordance with the Constitution of the USSR, which had been ratified by the Extraordinary Eighth Congress of Soviets of the USSR. The need for the RSFSR to adopt a new constitution stemmed from the economic and social changes that had taken place in the republic and in the Soviet Union as a whole. Such changes included the elimination of the exploiting classes, the enhancement of the moral and political unity of Soviet society, and the strengthening of friendship and cooperation among the peoples of the USSR.

M. I. Kalinin delivered a report on the draft of the new constitution. Under his chairmanship an editorial commission of 164 members examined amendments and additions to the draft and worked out a final text, which was ratified as the new constitution on Jan. 21, 1937. The congress adopted a resolution enjoining the All-Russian Central Executive Committee, elected at the Sixteenth All-Russian Congress of Soviets, to draft and ratify an election statute based on the new constitution and to establish a timetable for elections to the Supreme Soviet of the RSFSR.

EXTRAORDINARY SIXTH ALL-RUSSIAN CONGRESS OF SOVIETS OF WORKERS', PEASANTS', COSSACKS', AND RED ARMY DEPUTIES, a congress held from Nov. 6 to Nov. 9, 1918, in Moscow. The congress was attended by 1,296 delegates, of whom 963 were voting delegates. Of the voting delegates, 946 were Communists, 16 were members of other parties, and one was an unaffiliated delegate.

The agenda of the congress included elections to the All-Russian Central Executive Committee and a series of reports. V. I. Lenin delivered two of the reports, one dealing with the anniversary of the revolution and the other with the international situation. L. D. Trotsky spoke on military affairs; G. E. Zinoviev reported on building Soviet power in the central region of the country, on committees of the poor (*kombedy*), and on local soviets; and D. I. Kurskii spoke on the observance of socialist legality.

In his reports, Lenin summed up the principal achievements of the first year of Soviet power and outlined a program for Soviet domestic and foreign policy. The congress noted in its resolution On the International Situation that the international bourgeoisie was consolidating forces to suppress the growing revolutionary movement in capitalist countries and to stifle Soviet power in Russia. The resolution stressed the need to devote serious attention to strengthening the Red Army.

The congress approved proposing peace negotiations to the states waging war against Russia—the USA, Great Britain, France, Italy, and Japan. It saluted "all workers, peasants, and soldiers around the world who are fighting for peace and socialism, and their leaders," and it commended the Red Army and, for taking the city of Izhevsk, the Red Army soldiers and commanders of the Second Army of the Eastern Front. At the suggestion of the congress of committees of the poor of Severnaia Oblast, the delegates adopted the decree On the Organization of Model Regiments of Rural Poor. These regiments would draw from among "the most steadfast and reliable defenders of workers' and peasants' power."

With an eye to consolidating Soviet power, the congress adopted the decree On Amnesty, which released political prisoners who represented no danger to the Soviet republic. In the decree On Building Soviet Power in the Central Region, on Committees of the Poor, and on Local Soviets, the congress summarized the work of the committees of the poor and commissioned them to conduct new elections in all *volost* (small rural district) and village soviets. In the decree On Revolutionary Legality, the delegates called on all citizens of the republic, all bodies of Soviet power, and all public officials to observe the laws of the Soviet state strictly. The congress elected a new All-Russian Central Executive Committee, which consisted of 207 members and 39 candidate members.

EYADÉMA, GNASSINGBE (also Etienne Eyadéma). Born 1935 in Pya, Lama Kara District. State figure of Togo; general (1967).

From 1953 to 1962, Eyadéma served in the French Army in Indochina, Algeria, Niger, and Dahomey (since 1975, Benin). In January 1963 he took part in the military coup d'etat that overthrew President Olympio. In 1965 he became a lieutenant colonel and was appointed chief of staff of the Togolese armed forces. Eyadéma headed a new military coup d'etat in January 1967. Since April 1967 he has been president, head of the government, and minister of defense. Eyadéma is the chairman of the ruling and only party in the country, the Togolese Popular Rally (founded 1969). [29–1697–1]

EYRE, EDWARD JOHN. Born Aug. 5, 1815, in Hornsea, Yorkshire; died Nov. 30, 1901, near the city of Tavistock. British explorer of Australia.

In 1839, Eyre explored the Flinders Ranges and the valley of the Murray River, discovered Lake Torrens and Lake Eyre, and explored the Eyre Peninsula. In 1840 and 1841, he made a journey along the southern coast of Australia. The lake and peninsula named after Eyre are located in South Australia.

EYRE, the largest closed lake in southern Australia. Lake Eyre is located in a depression 12 m below sea level in an arid, desertlike region. It is filled with water only during the summer, when creeks flow into it periodically until it attains an area of 15,000 sq km and a depth of as much as 20 m. At other times it is a salt marsh. The lake was named in honor of E. J. Eyre. [29–1728–3]

EYRE, a peninsula in southern Australia between the Great Australian Bight and Spencer Gulf. Plains and depressions predominate, the maximum elevation being 200 m. The vegetation consists of thickets of brush eucalyptus and heaths. In the north the Gawler Ranges rise to a maximum elevation of 496 m. Sheep are

raised on the peninsula, and iron is extracted at the Iron Knob and Iron Monarch mines. The promontory was named in honor of E. J. Eyre. [29–1728–2]

EYSKENS, GASTON. Born Apr. 1, 1905, in Lierre, Antwerp Province. Belgian state and political figure; doctor of economic, political, and social sciences.

Eyskens studied at the University of Louvain and Columbia University. He became a professor at the University of Louvain in 1931. In 1939, Eyskens was elected to Parliament, where he was one of the leaders of the Christian Social Party. In 1945 and again from 1947 to 1949, he served as minister of finance; during the second term he served concurrently as deputy prime minister. He was prime minister in 1949 and 1950, from 1958 to 1961, and from 1968 to 1972. Eyskens served as minister of economic affairs in 1950 and as minister of finance in 1965 and 1966. [29–1729–6]

EZANA, king of the Aksumite Kingdom from about A.D. 325 to not later than 375. During Ezana's rule, the Aksumite Kingdom underwent major economic, political, and cultural development. Christianity began to spread in Aksum during the period.

EŽERĖLIS, an urban-type settlement in Kaunas Raion, Lithuanian SSR, 25 km west of Kaunas. The settlement has an enterprise for the processing of peat. [29–1693–3]

EZERO, an ancient multilevel settlement near the village of the same name in southeastern Bulgaria. Ezero was studied between 1952 and 1958 by V. Mikov and between 1961 and 1970 by the joint Bulgarian-Soviet expedition headed by G. Georgiev and N. Ia. Merpert. The cultural levels date from the Neolithic and Aeneolithic periods and the early Bronze Age (beginning of the fifth to the end of the third millennium B.C.).

The early Bronze Age level yielded the remains of 13 successive settlements surrounded by stone walls. The walls of the rectangular dwellings (10 × 4 m) were built of piles intertwined with branches and were coated with clay; within the dwellings were hearths and stoves with arches. Flint tools included sickle blades, knives, and end scrapers. Also discovered were axes, adzes, hammers, pestles, and saddlequerns made of bone, awls and hoes made of bone and antler, adzes, chisels, knives, and needles made of copper and bronze, and stone and clay casting molds. In addition, polished pottery with geometric designs was found, including pithos-like jars for storing grain, bowls, pitchers, and straight-walled pots. The population engaged in farming (barley and wheat) and stock raising (cows, sheep, goats, and hogs).

The finds in Ezero made it possible to identify the Bronze Age archaeological culture in southeastern Bulgaria (third millennium B.C.). The culture developed under the influence of the Baden culture and was linked with the Aegean and Anatolian cultures.

EZOP, a mountain range on the border between Khabarovsk Krai and Amur Oblast, RSFSR. The range has a length of 150 km and a maximum elevation of 1,906 m. The mountains are composed of granites and volcanogenic rocks. Up to an elevation of 1,200 m, the slopes are covered primarily by larch forests. [29–1695–2]

EZRA (also Esdras). Dates of birth and death unknown. A descendant of the Zadokites, high priests of the Temple in Jerusalem. Reformer of Judaism.

In the mid-fifth century B.C., Ezra arrived in Jerusalem at the head of a group of Jews returning from the Babylonian exile. He made changes in the ritual and appears to have carried out the first codification of the Pentateuch. In other reforms, Ezra prohibited marriages between Jews and those who had not converted to Judaism, and all Jews were obliged to learn the basic tenets of Judaism. It has been suggested that Ezra introduced a square Aramaic script, which gradually supplanted the Canaanite (Paleo-European) script. [29–1696–4]

FAMILY MEMBER, in jurisprudence, a person who has the rights and bears the duties that are based on family relations.

Soviet legislation does not provide a set definition of a family member. The norms of various branches of Soviet law, proceeding from the purposes of legal regulation and the nature of the relations regulated, give legal weight to various circumstances that determine the character of the relationship a person has with a family. These circumstances include kinship, dependence, joint residence with other family members, and the maintenance of a common household.

Legislation dealing with marriage and the family establishes the personal and property rights and duties of family members; the right to receive support payments is among these rights. Civil legislation determines the rights and duties of family members regarding, for example, inheritance and housing. Legislation on labor and social insurance covers the rights of family members to receive financial support or a pension in case of the loss or incapacitation of the breadwinner. Kolkhoz legislation establishes the mutual rights and obligations of family members with respect to the joint property of the family or kolkhoz household.

In certain circumstances, people enjoy various benefits or privileges, as established by law, by virtue of being members of a given family. For example, a person is entitled to receive a moving allowance if a member of his family is being transferred to a new place of work. In accordance with Article 34 of the Law on Universal Military Obligation of Oct. 12, 1967, a person enjoys the right to delay a call to active military service for reasons concerning members of his family. [29–669–1]

FEELER (or feeler gauge), a gauge that is used to inspect gaps between surfaces. A feeler is a thin strip with a specified thickness in the range from 0.02 to 1 mm. Feelers are usually manufactured as sets of strips of various thicknesses housed in a single case (Figure 1). The strips may be used individually or in various combinations. [29–1619–3]

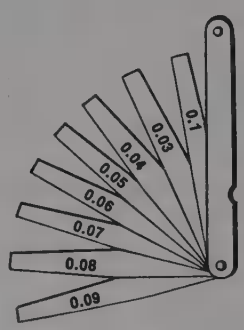

Figure 1. Feelers in a case

FEELING, in psychology, a peculiar type of emotional sensation distinctly object oriented in nature and comparatively stable. Feelings in this sense are related to a person's perception of some object, concrete or abstract, for example, a feeling of love for a human being or for the motherland. As a stable emotional attitude toward an object, feelings may not correspond to a person's emotional reaction to that object at a given moment. Human feelings are influenced by culture and history. Specific sign systems, including social symbols, ceremonial rites, and ritual acts, play an important part in the formation of feelings. [29–725–1]

FERROUS METALLURGY, a branch of heavy industry encompassing a group of interrelated subdivisions: ferrous metallurgy proper (blast-furnace production, steel production, rolling); pipe, tubing, and hardware production; mining, concentration, and sintering of ore materials; production of coke by-products; production of ferroalloys and refractory materials; mining of

non-ore materials for the industry; and secondary treatment of iron and steel. The industry's most important products are hot-rolled and cold-rolled products, steel pipe and tubing, and hardware.

Ferrous metallurgy is the basis for the development of most branches of the national economy. Despite the rapid growth in the output of the chemical industry, of nonferrous metallurgy, and of the building materials industry, iron and steel remain the primary building materials used in machine building and construction. In 1976 they accounted for more than 96 percent of the total volume of materials used by the leading branches of machine building in the USSR. Ferrous metallurgy consumes approximately 20 percent of the fuel and power resources of the USSR.

For several thousand years the development of human society has been inseparably linked with the use of iron as the major material for the production of the instruments of labor. V. I. Lenin called iron one of the bases of civilization and a primary product of modern industry (*Poln. sobr. soch.*, 5th ed., vol. 23, p. 377).

The production of iron in Russia has been known since antiquity. Iron ore was first smelted in low hearths and later (from circa the ninth century) in special bloomeries with blasting by means of hand bellows. The factory production of pig iron and iron began in the period 1632–37, when the first factory with a blast furnace for the production of up to 120 poods (approximately 1,965.5 kg) of pig iron per day was established near Tula. About 150,000 poods (2.457 million kg) of pig iron were produced in 1700. By the first quarter of the 18th century, iron production had increased by a factor of 5, and Russia led world production, maintaining its position until the beginning of the 19th century. However, the rate of growth of ferrous metallurgy subsequently decreased; by 1913, Russia was only the fifth largest producer in the world, accounting for 5.3 percent of the world production of iron and steel.

As a result of the Civil War and Military Intervention of 1918–20, steel production in the USSR in 1920 was only 4.5 percent of the 1913 level; by 1928, however, production had recovered to the prerevolutionary level. In the period of the five-year plans prior to World War II, old metallurgical enterprises were reconstructed, and new ones were built. A coal and metals base was created from the Ural Region and the Kuznetsk Coal Basin. Soviet ferrous metallurgy put into operation giant enterprises: the Magnitogorsk and Kuznetsk metallurgical combines, the Krivoi Rog and New Tagil metallurgical works, and the metallurgical plants Zaporozhstal' and Azovstal'. New open-hearth facilities were constructed at the Dzerzhinskii, Makeevka, Krasnyi Oktiabr', and Zlatoust plants.

Table 1. Production of pig iron, steel, iron and steel rolled stock, and steel pipe and tubing in the USSR
(million tons)

	1928	1940	1960	1970	1976
Pig iron	3.3	14.9	46.8	85.9	105.4
Steel	4.3	18.3	65.3	115.9	144.8
Finished rolled stock	3.2	11.4	43.7	80.6	101.4
Steel pipe	0.2	1.0	5.8	12.4	16.8

During World War II, the fascist German invaders destroyed plants yielding about 60 percent of the total steel production in the USSR. Iron and steel for the war effort were supplied by plants in the Urals and Siberia, where steel production was increased by a factor of 1.5. Plants were constructed in Kazakhstan and Uzbekistan, Soviet republics that previously did not have their own ferrous metallurgy.

The destroyed plants were restored very rapidly after the war. Between the 1950's and the 1970's, large new enterprises were constructed: the Orsk-Khalilovo and Karaganda metallurgical combines; the Cherepovets Metallurgical Plant and the Western Siberian Metallurgical Works; and a series of large mining and ore-enrichment combines and plants producing pipe, ferroalloys, hardware, and refractory materials. The modernization of obsolescent installations permitted a significant increase in their efficiency. In addition to considerable increases in production volumes, quality was improved and the range of metal products expanded. The manufacture of advanced types of iron and steel products developed rapidly, yielding a great effect on the national economy. Such products included rolled sheet stock, cold-rolled sheets, cold-rolled transformer steel, bent sections, high-precision shaped sections, low-alloy steel, high-strength pipe, iron powders, and cermets. Quality improvements in metal production and the extension and development of the product range provided the national economy with a saving of more than 2 million tons of iron and steel between 1971 and 1975.

The USSR occupies first place in the world in the manufacture of the most important products of ferrous metallurgy (steel, pig iron, iron ore, steel pipe and tubing, coke, and refractory materials). Production growth between 1928 and 1976 is shown in Table 1. As a result of the regular increase in production volumes, per capita steel production increased significantly from 305 kg in 1960 to 564 kg in 1976.

Iron and steel are produced in several economic regions of the RSFSR (Central, Central Chernozem, Ural, Volga, Western Siberia, Eastern Siberia, the Northwest, and the Far East) and the Ukraine (Donets-Dnieper Economic Region), as well as in Kazakhstan, Transcaucasia, Middle Asia, and the Baltic republics.

Ferrous metallurgy is characterized by a high level of production concentration, which is related to increases in the unit capacities of individual installations. Use is made of blast furnaces with working capacities of 5,000 cu m (Krivoi Rog Metallurgical Works), oxygen converters with capacities of 300–350 tons, model 3600 thick-sheet rolling mills, model 2000 continuous wide-band hot-rolling mills with a capacity of 6 million tons per year, and model 1700 five-stand cold-rolling mills with a capacity of more than 1 million tons per year. Iron ore enterprises with a capacity of 30 million tons of crude ore per year and large pipe-rolling and hardware factories are also in operation.

Enterprises of ferrous metallurgy typically feature various forms of integrated production. About 80 percent of steel production is at plants with complete metallurgical processing, combining blast-furnace, steel-smelting, and rolling operations. A number of enterprises and combines also have facilities for iron ore production, in addition to iron and steel manufacturing. Ferrous metallurgy is a branch of industry with a high level of specialization. More than 85 percent of steel pipe and tubing and 90 percent of commercial iron ore are produced at specialized plants.

The USSR has all the necessary resources for the development of ferrous metallurgy, including iron and alloy metal ores, fuel, and power resources; it occupies first place in reserves and volume of mined iron ore and mined commercial coal. The volume of iron ore extracted is sufficient to meet all the needs of Soviet ferrous metallurgy and to export significant amounts of ore concentrate, mainly to the member countries of the Council for Mutual Economic Assistance (COMECON). The USSR is also the leading producer and exporter of manganese and chromium ores. The major reserves of iron ore are found in the basin of the Kursk Magnetic Anomaly, the Krivoi Rog Iron Ore Basin, Kazakhstan, the Urals, Siberia, and the Kola Peninsula (*see* IRON INDUSTRY).

The fuel base for ferrous metallurgy consists of deposits of coking coals found mainly in the Donets, Karaganda, and Pechora basins and deposits of natural gas in European Russia, Siberia, and Middle Asia.

Soviet ferrous metallurgy has a high engineering potential. Significant progress has been achieved in production engineering in individual subbranches and production divisions in the industry. The mining of iron ore is conducted primarily with advanced open-pit techniques, and smokeless charging and dry-process coke quenching have been introduced into coke production (*see* BY-PRODUCT COKE INDUSTRY). In blast-furnace production, 97 percent of the pig iron produced in 1976 was made in furnaces with high gas pressure, and 84 percent was produced by means of natural gas blasting. In steel production, smelting in basic oxygen and electric furnaces is increasing, and steel refining under vacuum, with synthetic slags, and with inert gases outside the furnace has been introduced. Other innovations include remelting with electroslag, vacuum induction, and electron-beam techniques and through the use of arc vacuum and plasma furnaces. The use of continuous steel casting is increasing, and heat treatment of metal products and methods of nondestructive automatic control

are being used effectively in rolling operations. In pipe and tubing production, the technology for manufacturing welded pipe of large diameter and seamless pipe is being improved (*see* TUBE ROLLING and PIPE AND TUBING INDUSTRY). Automated production lines are being introduced in hardware manufacture, and industrial methods for the direct reduction of iron ore are under development. Work is being conducted on the creation of an automated system for industry management.

Much attention is being devoted in the industry to the mechanization and automation of production processes, improvements in the organization of production and labor, and questions of socialist competition. During the ninth five-year plan (1971–75), virtually all increases in production volume in ferrous metallurgy were achieved as a result of increased labor productivity, that is, without an increase in the number of workers.

Table 2. Steel production in the COMECON countries
(million tons)

	1960	1970	1976
Bulgaria	0.3	1.8	2.5
Cuba	—	0.1	0.3
Czechoslovakia	6.8	11.5	14.7
German Democratic Republic	3.8	5.1	6.7
Hungary	1.9	3.1	3.7
Poland	6.7	11.8	15.6
Rumania	1.8	6.5	10.7

Ferrous metallurgy is also developing successfully in other socialist countries. As a result of an increase in production volumes, the contribution of the COMECON countries to world steel production (together with the USSR) increased from 24.9 percent in 1960 to 28.8 percent in 1976. Data on steel production in the COMECON countries are given in Table 2.

In 1976, Czechoslovakia produced 9.5 million tons of pig iron; Poland, 7.9 million tons; Rumania, 7.4 million tons; and the German Democratic Republic, 2.5 million tons. In 1975, Czechoslovakia produced 10.0 million tons of iron and steel rolled stock; Poland, 11.1 million tons; Rumania, 6.8 million tons; and the German Democratic Republic, 5.2 million tons.

The socialist countries are actively cooperating with the developing countries in efforts to establish and expand ferrous metallurgy. By 1977, with the assistance of the USSR, metallurgical works were constructed in many countries, including India, Egypt, and Iran, with annual production capacities of 7.2 million tons of pig iron, 5.3 million tons of steel, 4.1 million tons of rolled stock, and 6.7 million tons of mined iron ore. Metallurgical production complexes with capacities of 11–14 million tons of steel and rolled stock are in the planning stage or under construction.

In the capitalist countries, ferrous metallurgy is most developed in the USA and Japan. The Federal Republic of Germany (FRG), Great Britain, France, and Italy are also large producers of iron and steel (see Table 3).

Table 3. Steel production in the industrially developed capitalist countries
(million tons)

	1960	1970	1976
USA	92.1	122.0	120.0
Japan	22.1	93.3	107.0
Federal Republic of Germany	34.1	45.0	42.4
Great Britain	24.7	28.3	22.7
France	17.3	23.8	23.0
Italy	8.2	17.3	23.3

In 1976, Japan produced 86.0 million tons of pig iron; the USA, 79.8 million tons; and the FRG, 32.3 million tons. In 1975, Japan produced 86.3 million tons of iron and steel rolled stock; the USA, 72.5 million tons; and the FRG, 33.0 million tons.

Ferrous metallurgy in the capitalist countries is characterized by a high degree of monopolization of production. Thus, five companies account for 80 percent of the steel production in Japan and about 60 percent in the USA. Six companies account for more than 75 percent of the steel production in the FRG. Two companies account for 65 percent of the steel production in France, and one company in Great Britain accounts for more than 85 percent of the country's steel production (*see* IRON AND STEEL MONOPOLIES).

World steel production totaled 192 million tons in 1950, 463 million tons in 1965, and 690 million tons in 1976. The number of steel-producing countries increased from approximately 50 in 1965 to 65 in 1976. Characteristic of the development of ferrous metallurgy is the rapid increase in the scale of the world market for iron and steel: exports of iron and steel products from producer countries more than doubled between 1965 and 1976.

FERROUS METALLURGY, INSTITUTE OF (full name, I. P. Bardin Central Scientific Research Institute of Ferrous Metallurgy; TsNIIchermet), an institute under the administration of the Ministry of Ferrous Metallurgy of the USSR.

The Institute of Ferrous Metallurgy was founded in 1944 on the initiative of I. P. Bardin, after whom it was named in 1960. The world's largest research organization in ferrous metallurgy, it has six specialized subdivisions: the Institute of New Metallurgical Technology, the Institute of Precision Alloys, the Institute of Quality Steels, the Institute of Metal Science and Metal Physics, the Institute of the Economics of Ferrous Metallurgy, and the Institute of Standard Samples. TsNIIchermet also includes an experimental plant and departments dealing with, for example, standardization and coordination.

The institute has developed new techniques applicable to such processes as the basic oxygen process and continuous steel casting and has created new steels, alloys, and composites. Fundamental aspects of the theory of metallurgical processes are studied at the institute, which confers the degrees of doctor of sciences and candidate of sciences. TsNIIchermet publishes 12 specialized industrial journals. It was awarded the Order of the Red Banner of Labor in 1969. [29–287–3]

FICARIA (lesser celandine), a genus of plants of the family Ranunculaceae. The genus is related to the genus *Ranunculus*, in which it is frequently included. The plants are perennial herbs with tuberous root sections. The stem is usually reduced, and the leaves are entire and mainly fleshy. The flowers are solitary, with yellow or golden petals. The fruit is a multiple nut with small swollen achenes. There are eight to ten species (or three to five species, with several subspecies). The plants are native to Eurasia. The USSR has five or six species. *F. verna* grows in the European USSR, Western Siberia, the Caucasus, and to a lesser extent, Middle Asia; the plant occurs in humid places, primarily in meadow-forest regions. [29–647–2]

FILLER, a pasty substance used in painting and varnishing to produce a smooth surface before the surface coat is applied. In addition to film-forming materials, fillers contain extenders such as chalk, talc, and barite as well as pigments such as zinc white and ocher. Fillers may have a varnish, drying-oil, or natural-adhesive base. Since the content of film-forming materials in a filler is 5–12 times lower than that of pigment or extender, fillers do not provide for a sure adhesion of the covering coats to the surface. For this reason, a filler is usually applied over a layer of primer.

A thick filler is applied with a putty knife or a piece of rubber. A filler thinned with small amounts of solvent may be applied with a pneumatic spray gun. The thickness of a layer of filler may

reach 300 μ; when a filler is used to fill holes or to seal a joint or a riveted or welded seam, however, several layers with a total thickness of up to 1 mm may be required. The dried-up layer of filler must be sanded well with an abrasive paper. Varnish-based fillers are used mainly in the machine-building industry; fillers with a natural-adhesive or drying-oil base are used primarily in the construction industry.

FINE, a monetary exaction; a means of applying financial pressure in certain cases, and in accordance with a certain procedure, established by law.

Under Soviet civil law, the fine is a type of penalty for nonfulfillment or improper fulfillment of a contract obligation. The amount of the fine is either a fixed sum or a set percentage of the value of the obligation; it is determined at the time the contract is drawn up as a means of ensuring the proper fulfillment of the contract. The fine establishes liability for violating the contract. The fine must be paid only when the party that failed to fulfill its obligation is at fault, although fines are recovered regardless of fault in exceptional cases, as provided by the contract or by law; for example, fines are exacted when the plan for rail transport of goods is violated. The fine is widely used by socialist organizations as an effective means of applying pressure to a contracting party that violates its agreement to provide supplies, to transport goods, or to perform other services.

In Soviet criminal law, the fine is used as a primary and supplementary measure of punishment for certain crimes, as provided by the Basic Principles of Criminal Legislation of the USSR and of the Union republics and the criminal codes of the Union republics. A court may also impose a fine as a way of substituting a milder punishment for the unserved part of a sentence. A fine may be imposed as a supplementary punishment in cases of conditional conviction.

The amount of the fine is established by the court and depends on both the seriousness of the crime and the financial situation of the guilty party. If it should be impossible to exact a fine, the court may convert the fine to a sentence of correctional labor without deprivation of freedom; in such cases, one month of correctional labor is substituted for each ten rubles of the fine, but the sentence cannot exceed one year. The court is not permitted to convert a fine to a sentence of deprivation of freedom or vice versa. The procedure for the payment of a fine is determined at the time of sentencing.

Under Soviet administrative law, fines are imposed on persons guilty of administrative violations. The grounds and procedure for the imposition of fines, the amounts of fines, and the state agencies and officials empowered to impose them are determined by the legislation of the USSR and the Union republics. As a rule, an administrative fine that is imposed on an ordinary citizen should not exceed ten rubles, and one imposed on an official should not be greater than 50 rubles; in certain cases specified by law, however, the limits may be raised to 50 and 100 rubles, respectively. In exceptional cases that pertain to the fulfillment of obligations under international treaties of the USSR, or necessitate an increased administrative liability, still greater fines, specified by legislative acts of the USSR, may be imposed (Basic Principles of Civil Legislation of the USSR and the Union Republics, art. 14). An administrative fine may be imposed only on a citizen or official. Such fines may be imposed by people's judges (in such cases as petty hooliganism); by administrative commissions attached to the executive committees of soviets of raions, cities, settlements, and villages (in such cases as violation of public order and the regulations of public amenities); by the militia; and by authorized agencies and officials that are responsible for such areas of public protection as fire safety, sanitation, and quarantine of animals.

An administrative fine of up to 30 rubles may be imposed on parents or guardians of minors by commissions on juvenile affairs if the parent or guardian mistreats the child, willfully neglects obligations for the proper upbringing of the child, or brings a minor into a state of drunkenness. A parent or guardian may also be fined if a law is violated by the child.

An order imposing a fine may be appealed by the person concerned or by the aggrieved person to a higher administrative agency or a people's court in raions and cities within ten days from the date the order is ruled. The submission of an appeal suspends the procedure for collecting the fine until the appeal is considered. A fine must be paid not later than 15 days from the delivery of the order; in case an appeal or a protest has been submitted, it is to be paid not later than 15 days from the delivery of a notice dismissing the appeal or the protest. A fine that has not been paid within the specified time is collected by enforcement measures from the wages of the offender on the order of the agency or the official that imposed the fine. In those cases in which the offender is unemployed, the fine is recovered by levying execution on his property by an officer of the court in compliance with the rules specified by law.

Under Soviet procedural law, courts may impose fines of specific amounts in certain cases, as provided by procedural legislation. These cases include the nonfulfillment of procedural obligations by a party to a proceeding and disorderly conduct in court.

As a measure of social influence, a fine may be applied in certain situations by a comrades' court. [29–1492–1]

FIRECLAY, refractory clay or kaolinite, which when roasted loses plasticity, the chemically bound water is removed, and a certain degree of sintering occurs. The Russian term for "fireclay"—*shamot*—is also applied sometimes to certain other initial materials used in the production of refractories, roasted to obtain pelletized powders (often in a clay mixture) and to stabilize the properties of the material (high-alumina, corundum, and zircon fireclays).

Fireclay is obtained by roasting—in rotary, shaft, or other furnaces at temperatures of, for the most part, 1300°–1500°C—the raw material, which is in the form of natural pieces or briquettes prepared in belt, roller, and other presses. The degree of sintering of fireclay is characterized by water absorption, which is usually between 2–3 and 8–10 percent, but can be as high as 20–25 percent for "low-roasted" fireclay. After fragmentation and grinding, fireclay is used as a component (to reduce plasticity and shrinkage during drying and roasting) of bulk fireclays in molding articles (or correspondingly, high-alumina and other refractory materials). It is also used in the production of mortars and bulk gunite and as an aggregate in refractory concrete. In the mid-20th century, fireclay came to be used in sculpture, primarily for small statuettes.

Khimicheskaia tekhnologiia keramiki i ogneuporov. Moscow, 1972. [29–824–2]

FIRECLAY REFRACTORY, the most common type of aluminosilicate refractory product. Fireclay refractories contain 28–45 percent Al_2O_3. They are made from refractory clays and kaolins cut by the addition of fireclay or, sometimes, nonplastic clay rocks and quartz. They are used in blast, reheating, and roasting furnaces; they are also used in pouring steel and in other operations.

FOCAL-PLANE SHUTTER, a camera shutter positioned near the focal plane of the lens, consisting of two opaque blinds that form a slit of variable width or a single blind with a slit cut in it. [29–1486–2]

FORD RANGES (also Edsel Ford Ranges), mountains in the northwestern part of Marie Byrd Land in western Antarctica between 140° and 149° W long. The mountains are composed of metamorphized terrigenous and carbonate deposits, as well as granodiorites and granite. The greater part is covered by glacial ice. Individual peaks, which are divided by deep depressions with valley glaciers, rise above the glacial surface to a maximum elevation of 1,370 m at Mt. Avers. They were discovered in 1929 by an

American expedition led by R. Byrd. They were named in honor of Edsel Ford, who provided financial support for the expedition. [29–1690–1]

FOREMEN'S SCHOOLS AND CLASSES, in the USSR, schools and classes in which workers may receive instruction without leaving their jobs. In addition to providing a general education, the foremen's schools enable students to receive advanced training and increase their technical knowledge. Skilled workers and foremen with practical experience who do not have a complete secondary education attend these schools and classes.

Foremen's schools, which were first established in 1962 at large enterprises and cover the ninth through 11th grades, are set up when there are at least 100 potential students. When the number is less than 100, special foremen's classes, also covering the ninth through 11th grades, are created within evening (shift) secondary general-education schools; this system was introduced in 1964. The general-education subjects in foremen's schools and classes follow the syllabi of the secondary school; specialized subjects are based on syllabi approved by the management of the enterprise. In addition to receiving a certificate of secondary education, graduates of the schools and classes, upon passing additional qualifying examinations, are eligible to hold the position of foreman or chief of a production section.

FOUR ARTS (full name, the Society of Artists of the Four Arts), an artistic association active in Moscow from 1924 to 1931. The Four Arts was founded mainly by former members of the World of Art and the Blue Rose. It included Soviet painters, graphic artists, sculptors, and architects primarily of the older generation: L. A. Bruni, I. S. Efimov, I. V. Zholtovskii, K. N. Istomin, A. I. Kravchenko, P. V. Kuznetsov, N. N. Kupreianov, A. T. Matveev, V. I. Mukhina, A. P. Ostroumova-Lebedeva, K. S. Petrov-Vodkin, M. S. Sar'ian, V. A. Favorskii, and A. V. Shchusev.

Members of the association strove for high professional quality, as well as an expressive decorative style. In architecture, they advocated the reworking of principles of modern city planning. The Four Arts organized exhibitions in Moscow in 1925, 1926, and 1929 and in Leningrad in 1928.

FOUR-BAR LINKAGE, a plane mechanism consisting of four links that form rotating kinematic pairs. A four-bar linkage (Figure 1) consists of a fixed link (0, the base), two rotating links (1 and 3), and a connecting link (2), which is also called a connecting rod or coupler. A rotating link is called a crank if it can undergo a complete rotation with respect to the axis of rotation; it is called a rocker if it can undergo only part of a rotation.

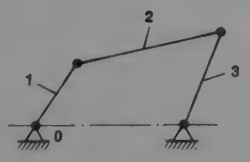

Figure 1

Depending on the type of rotating links present, four-bar linkages are subdivided into crank-and-rocker, drag-link, and double-rocker types. A crank-and-rocker mechanism is used to convert the constant rotation of the crank into the reciprocal motion of the rocker. In manufacturing machinery, the crank is set in motion by a main shaft, and a working member that performs a given production operation is connected to the rocker. A drag-link mechanism converts uniform rotation into nonuniform rotation in a single direction; it is used in machines where the working member, while moving in a single direction, must have a velocity that significantly exceeds the average velocity on some segment. Double-rocker linkages are used chiefly in instruments to provide a mechanical reproduction of a given function, such as $y = \log x$. Four-bar linkages are also used to reproduce the motion of a point along a given curve; for example, the Chebyshev parallel motion can be used to approximate a segment of a straight line.

N. I. LEVITSKII [29–864–1]

FOUR-COLOR PROBLEM, the problem of whether four different colors are sufficient to color any map so that no two regions having a common boundary segment have the same color. Although the conjecture that four colors are enough was proved for all known special cases, the problem long remained unsolved. Not until 1976 was a report of a rigorous mathematical proof published.

First formulated as a mathematical problem in the mid-19th century, the four-color problem became widely known through the lectures of the British mathematician A. de Morgan. A rigorous formulation of the problem requires that the regions in question be bounded by Jordan curves—that is, by simple closed curves. It can be easily proved that five colors are always sufficient to color such a map.

In the corresponding problem for space, no number of colors is sufficient.

FOUR-CYCLE ENGINE, an internal combustion engine with an operating cycle consisting of four piston strokes that occur in the course of two revolutions of the crankshaft.

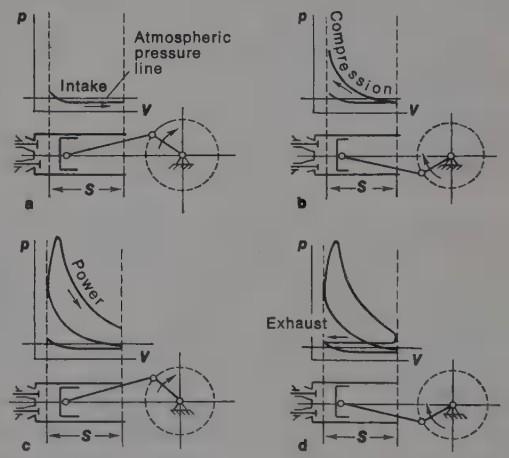

Figure 1. Operation of a carburetor-type four-cycle engine: (a) intake, (b) compression, (c) power, (d) exhaust; (*p*) cylinder pressure, (*V*) effective cylinder volume, (*S*) distance traveled by piston

The first two strokes, the intake and compression strokes, occur during the first revolution of the crankshaft. The intake of the fuel mixture in a carburetor engine or a spark-ignition engine or of the air in a diesel engine occurs as the piston moves from top dead center to bottom dead center. The compression of the fuel mixture or of the air is accomplished as the piston moves from bottom dead center to top dead center.

The power stroke, in which the piston moves as it does during intake, and the exhaust stroke, in which the piston moves as it does in compression, occur in the second revolution of the crankshaft. The power stroke, during which the fuel mixture undergoes combustion and expansion, results from the pressure of the combustion products on the piston. During the exhaust stroke, the final stroke, the combustion products are removed from the cylinder.

The intake, compression, and exhaust strokes are accomplished by means of the kinetic energy stored during the power

stroke in the crankshaft and in the parts connected to it when the chemical energy of the fuel is converted into the mechanical energy of the moving parts of the engine.

Lasting for only a fraction of a second, combustion is accompanied by a rapid increase in the forces acting on the cylinder head, the piston, and other engine parts. Consequently, the weight of the moving parts must be increased in order to strengthen them. An intrinsic drawback of the piston engine is that this increase in weight is accompanied by an increase in the inertial force on the moving parts.

Figure 1 shows the dependence of the pressure p in the cylinder of a four-cycle engine on piston position in each stroke.

The power stroke in a one-cylinder four-cycle engine is accompanied by three nonpower strokes. In a two-cycle engine, however, there is only one nonpower stroke. Consequently, a one-cylinder four-cycle engine runs rougher than a one-cylinder two-cycle engine. For smoother running, four-cycle engines are manufactured with large flywheels or with several cylinders. The operating cycle of a four-stroke rotary-piston engine is analogous to the operating cycle of the four-cycle engine, with the exception that, in the rotary engine, the cycle is completed in one rotor revolution. IU. A. ZARIANKIN [29–364–3]

FOUR FAMILIES OF CHINA, a reactionary Kuomintang coalition that ruled China from 1927 through 1949. The Four Families, which were headed by Chiang Kai-shek, were made up of members of the families of Chiang Kai-shek, Sung Tzu-wen, K'ung Hsiang-hsi and of the brothers Ch'en Kuo-fu and Ch'en Li-fu. After seizing power and establishing their control over the country's monopolies, they subjected the Chinese people to cruel exploitation. In 22 years of rule they accumulated capital in excess of $20 billion. The Four Families relied on the support of the imperialist powers, especially the USA, whose position in Kuomintang China was noticeably strengthened. After the triumph of the people's revolution in 1949, the assets of the Four Families were confiscated and became the state property of the People's Republic of China.

FOUR-HORNED ANTELOPE (*Tetracerus quadricornis*), a ruminant of the family Bovidae. The four-horned antelope is a small, slender animal, with a body length reaching 1 m and a tail length of 10–15 cm. It weighs 15–25 kg. The antelope is the only member of the family Bovidae whose male has four horns—two slightly curved rear horns measuring 8–10 cm long and two straight front horns measuring 2.5–4 cm long. The females are hornless. The body is cinnamon brown, with lighter underparts. The legs are white on the inside; the edges of the snout and the outside of the ears are black.

The four-horned antelope is distributed in India, where it is found in sparse forests and near reservoirs. It lives secretively, in pairs or singly. The diet consists of grass and leafy shrubs. Mating occurs in August, and one to three young are born in January or February. The animal is hunted for its valuable horns. [29–363–1]

FOURHORN SCULPIN (*Myoxocephalus quadricornis*), a fish of the family Cottidae. The fish measures as much as 37 cm in length and reaches 500 g in weight. Two pairs of bony protuberances on the head are highly developed in ocean forms and poorly developed or absent in lake forms.

The fourhorn sculpin is distributed along the shores of the northern Arctic Ocean, the Baltic Sea, the lakes of Northern Europe, and the Great Lakes of North America. It feeds on crustaceans and fish. It reproduces in winter. The fish is edible but has no commercial importance.

FOURTEEN POINTS, the conditions for peace, as formulated in 14 articles by President W. Wilson of the USA at the end of World War I in an address to Congress on Jan. 8, 1918.

The Fourteen Points consisted of the following aims: (1) open covenants of peace openly arrived at; (2) absolute freedom of navigation ("freedom of the seas"); (3) abolition of trade barriers ("freedom of trade"); (4) establishment of disarmament guarantees; (5) settlement of colonial claims; (6) evacuation by Germany of all occupied Russian territories and the granting to Russia of the opportunity to determine its own political development; (7) evacuation and restitution of Belgium; (8) the return of Alsace-Lorraine to France and the restoration of occupied regions to France; (9) the readjustment of Italian frontiers along lines of nationality; (10) autonomous development for the peoples of Austria-Hungary; (11) evacuation by Germany of the occupied territories of Rumania, Serbia, and Montenegro, with an outlet to the sea for Serbia; (12) opportunity for autonomous development for the non-Turkish portions of the Ottoman Empire and freedom of shipping through the Dardanelles for all nations; (13) the creation of a Polish state; and (14) the creation of the League of Nations.

The Fourteen Points represented an imperialist program for peace based on the establishment of the hegemony of the USA in international affairs. In particular, the "freedom of trade" was to open world markets for the economically most powerful country—the USA. The "freedom of the seas" was directed against the British Navy's control over world trade routes. The slogan "disarmament" was calculated to weaken the military might of Great Britain and Japan. One of the essential goals of the Fourteen Points was to mask the expansionist aims of US foreign policy, which was especially necessary with regard to the enunciation by Soviet Russia of a democratic and just peace, which was contained in the Decree on Peace. [29–371–1]

FOURTEENTH ALL-RUSSIAN CONGRESS OF SOVIETS OF WORKERS', PEASANTS', AND RED ARMY DEPUTIES, a congress held in Moscow from May 10 to May 18, 1929. The congress was attended by 1,158 voting delegates and 626 with observer status. Industrial workers made up 57.1 percent of the delegates, peasants, 25 percent, and nonindustrial workers, 17.9 percent. Of the delegates, 70.7 percent were members or candidate members of the ACP(B), 1.2 percent were members or candidate members of the Komsomol, and 28.1 percent were not party affiliated.

The agenda of the congress included elections to the All-Russian Central Executive Committee and a series of reports. A. I. Rykov gave the report of the government of the RSFSR, A. I. Lezhava spoke on the five-year plan for the development of the republic's economy, and A. V. Lunacharskii dealt with the tasks of cultural construction. In addition, A. B. Khalatov spoke on the state of Soviet book publication after ten years, A. S. Kiselev reported on lower-echelon soviets and the strengthening of their powers, and Ia. V. Poluian explained changes in and additions to the Constitution of the RSFSR.

The congress approved the activities of the government of the RSFSR and adopted the first five-year plan for the development of the economy of the RSFSR (1929–32). After making a positive assessment of the country's accelerated rate of industrialization, the congress enjoined the government to intensify its efforts in the socialist reorganization of agriculture. The congress appealed to urban and rural working people to help fulfill the five-year plan and to promote socialist competition in every way possible. In a resolution concerning cultural construction, the congress emphasized the need to pay special attention to the work of implementing universal compulsory elementary education and of eliminating illiteracy among the adult population.

The program for the socialist reconstruction of the economy required improved functioning of government bodies, especially at the local level. The congress called upon the All-Russian Central Executive Committee to reexamine the Statute on Rural Soviets for the purpose of broadening their powers in organizational, economic, and cultural work as well as in serving the everyday needs of the peasantry. The congress directed the Central Executive Committee to devise measures to combat breaches of revolu-

tionary legality and to put an end to the terrorist activities of the kulaks.

A resolution was passed recommending that soviet agencies be purged of alien elements and that new cadres be formed from among workers, farmhands, the poor, and party-minded middle peasants. The congress amended several articles of the Constitution of the RSFSR to reflect the completion of regionalization, the introduction of new administrative and territorial divisions, and the expansion of the powers of the local soviets. A new All-Russian Central Executive Committee was elected, with 400 members and 150 candidate members.

[29–368–1]

FOURTEENTH CONFERENCE OF THE RUSSIAN COMMUNIST PARTY (BOLSHEVIK), a conference held in Moscow from Apr. 27 to Apr. 29, 1925. The conference was attended by 178 voting delegates and 392 with observer status. The agenda included a series of reports. V. M. Molotov presented a report on aspects of party organization, A. I. Rykov spoke to the conference on cooperation, and A. D. Tsiurupa read a report on the agricultural tax. In addition, F. E. Dzerzhinskii gave an account of the metallurgical and machine-building industry, G. E. Zinoviev reported on the enlarged plenum of the Executive Committee of the Communist International, and A. A. Sol'ts spoke to the delegates on the revolutionary legality.

The primary work of the conference centered on the prospects of building socialism in the USSR. This question was of paramount importance because the economy had approached prewar levels and, consequently, problems associated with its modernization were arising. Drawing attention to capitalist encirclement of the Soviet Union, the partial stabilization of capitalism, capitalist suppression of the revolutionary movement in a number of countries, and the economic backwardness of Russia, the Trotskyists and the leaders of the New Opposition, Zinoviev and L. B. Kamenev, argued that it would be impossible to build socialism in the USSR without outside help.

The Central Committee rejected Zinoviev's draft theses "On the Tasks of the Comintern and the RCP(B) in Connection With the Enlarged Plenum of the Executive Committee of the Communist International," in which he stated that the victory of socialism could be achieved only on an international scale. The Central Committee reworked the theses to support the Leninist position that the victory of socialism in the USSR was possible at a time when the growth of the world revolution was slackening.

The conference unanimously approved the Central Committee's theses (Zinoviev and Kamenev did not express their views on the revised theses during the conference). It pointed out that the Soviet Union had all the prerequisites for the creation of a socialist society and that an alliance of the working class and the toiling peasantry would be able on its own to defeat capitalism within the country not only politically but also economically. Inasmuch as capitalist encirclement of the USSR presented the danger of intervention and of the restoration of capitalism in the country, a resolution was adopted stressing that the final victory of socialism, which would provide a full guarantee against the restoration of bourgeois relations, would be possible only if proletarian revolutions were successful in a number of countries.

Other discussion centered on the immediate tasks of economic construction. It was suggested that the development of the metallurgical and machine-building industry be accelerated, that a three-year plan be prepared for the industry, and that construction of new metallurgical plants begin. It was also proposed that production of nonferrous metals be expanded and that more attention be devoted to increasing the productivity of labor and to improving the quality of output. The conference pointed out the need for maximum cooperation in all phases of rural economic life. In order that the influence of the poor and middle peasants be enhanced through cooperation, it was recommended that kulak elements not be permitted in the governing bodies of cooperative associations. The conference rejected N. I. Bukharin's politically incorrect notion that kolkhozes were not the highroad to socialism for the peasantry, and it urged that greater emphasis be placed on the establishment and strengthening of kolkhozes. It was decided that the method for determining the agricultural tax should be based on farm size, thus serving the interests of the poor and middle peasants.

The resolution On Building the Party established a goal of improving party leadership in all branches of the economy, especially in the rural sector. It was decided that at least 1,000 Communists would be sent to district and *volost* (small rural district) RCP(B) committees and that, for the purpose of raising the level of ideological and educational work in the villages, at least 3,000 propagandists would be sent. The conference devoted special attention to the need to provide sound leadership for the peasantry from the ranks of the proletariat and to strengthen the alliance with the middle peasants in order to enlist them in the building of socialism. To reinforce the leadership of the mass organizations of working people, it was suggested that the Communist factions in the soviets, the trade unions, and the cooperative bodies be strengthened and that the party nucleus in the Komsomol be enlarged. The conference called for strict observance of socialist legality and for an intensification of the struggle against bureaucracy and infractions of state discipline.

The conclusion of the conference that the victory of socialism was possible in the USSR was put in the form of a party resolution, which obliged every Communist to take an active part in socialist construction and to rally the working people of the country around the achievement of this goal.

S. S. SHAUMIAN [29–366–1]

FOURTEENTH CONGRESS OF THE ALL-UNION COMMUNIST PARTY (BOLSHEVIK), a congress held from Dec. 18 to Dec. 31, 1925, in Moscow. The congress was attended by 665 voting delegates and 641 with observer status. The delegates represented 643,000 party members and 445,000 candidates for membership.

The agenda of the congress included the political report of the Central Committee, delivered by J. V. Stalin; the organizational report of the Central Committee, read by V. M. Molotov; the report of the Auditing Commission given by D. I. Kurskii; the report of the Central Control Commission presented by V. V. Kuibyshev; and the report of the RCP(B) delegation in the Executive Committee of the Comintern, read by G. E. Zinoviev. In addition, M. P. Tomskii gave an account of the work of the trade unions, N. I. Bukharin reported on the work of the Komsomol, and A. A. Andreev spoke on alteration of the party Rules. Elections were held, and at one of the sessions the congress heard G. V. Chicherin's report on the international situation and Soviet foreign policy.

During the preparation for the congress and during the congress itself, an intense struggle was waged against the New Opposition, a faction that had taken issue with the party's course in implementing Lenin's plan for building socialism in the USSR and was attempting to revise the political line of the Central Committee from a Trotskyist position. The leaders of the faction—Zinoviev and L. B. Kamenev—had decided to make the Leningrad party organization a strongpoint in the struggle against the Central Committee. Through deception and flagrant violation of internal party democracy, they had arranged to have the delegation to the congress from the Leningrad organization consist solely of their confederates. Since the overwhelming majority of Leningrad Communists were faithful to the Central Committee of the RCP(B), the leaders of the New Opposition camouflaged their adoption of Trotskyist positions.

In its political report the Central Committee set forth its line on the fundamental questions of socialist construction. The committee stressed that a balance of power had been established in relations between the Soviet Union and the capitalist states as a

result of the inherent weakness of world capitalism and the growth of the revolutionary movement around the world.

Of primary importance to the country's international standing was the economic and political consolidation of the USSR and the achievement of an environment that would enable peaceful coexistence with the capitalist countries. The congress pointed to the need to continue a policy of peace while strengthening the defense capability of the USSR. In a resolution on the report of the Central Committee, the congress expressed complete solidarity with the revolutionary struggle of the proletariat and oppressed peoples of the world and declared that the party would strengthen the alliance between them and the toiling masses of the USSR and would give them support.

The Central Committee's report also noted that in building socialism the party strictly adhered to the Leninist general line, which regarded heavy industry as the foundation of the socialist transformation of the economy. The Central Committee's position in favor of preferential development of heavy industry was approved, and a directive was issued "to continue the industrialization of the country and the development of the production of the means of production" (*KPSS v rezoliutsiiakh*, 8th ed., vol. 3, 1970, p. 247).

Outlining a program designed specifically to draw the middle peasantry into socialist construction by means of cooperation, the congress stressed that if the poor, and especially the farmhands, were the foundation of the rural working class, then the middle peasant should be a staunch ally of that class.

The New Opposition challenged the measures devised by the party to implement Lenin's plan for building socialism. On the second day of the congress, the faction demanded the floor in order that Zinoviev might deliver a supplementary statement on the report of the Central Committee. The New Opposition thereby announced its disagreement with the political line of the Central Committee.

Exaggerating the difficulties of socialist construction, Zinoviev tried to persuade the delegates that building socialism in an economically backward country was doomed to failure. Rationalizing its own divisive and factional behavior, his group accused the Central Committee of a myriad of errors. Like Trotsky in 1923 and 1924, it was seeking to seize control of the party leadership. It wanted to alter the composition of the Politburo and to remove from his position as general secretary of the Central Committee J. V. Stalin, who, with the support of the majority of the members of the party, was leading the struggle against the opposition. The New Opposition was prepared to bring about a split in the party, a danger against which Lenin had warned.

Adopting a position of silent support of the New Opposition, Trotsky did not take the floor at the congress and concealed his plan to unite with the faction (*see* TROTSKYIST-ZINOVIEVIST BLOC). The delegates to the congress rebuffed the New Opposition and exposed the Trotskyist-Menshevik nature of its platform. The congress approved the political and organizational line of the Central Committee, censured the attempts of the anti-Leninist elements to pervert the fundamental principles of party politics and theory, and authorized the Central Committee "to wage a determined struggle against all attempts to undermine the unity of the party, no matter where they originate" (*ibid.*, p. 252). Of the 653 delegates who participated in a roll-call vote on the resolution on the report of the Central Committee, only 65 voted against it. The opposition's isolation in the congress was apparent.

In the resolution On the Report of the Central Control Commission, the congress approved the position taken by the commission on the defense of party unity and on the support of the Leninist line of the Central Committee. The congress urged the new members of the commission "to fight even more resolutely against ideological vacillation and attempts to violate the common will and discipline of the party" (*ibid.*, p. 253).

The tasks associated with the reconstruction of the country required improved functioning of government bodies. The congress approved the work of the organs of state and party control and made an appeal in the resolution On the Work of the Central Control Commission and the Workers' and Peasants' Inspectorate for an intensification of the struggle against bureaucracy and for an improvement of the manner and methods of operation of state institutions.

After taking a stand against strengthening party control of trade unions and after propagandizing for the "independence" of the Komsomol from the party, the New Opposition was again rebuffed. It was pointed out in several resolutions that the trade unions could accomplish their tasks only under the leadership of the party. The congress called for recognition of the full and unconditional authority of the party and its Central Committee in the guidance of the Komsomol. The opposition's demand for the unlimited expansion of party ranks was rejected, since such expansion could lead to the end of the party's role as a politically aware organized forward detachment of the working class. It was proposed that internal party democracy be improved and that the level of activity of the broad masses of Communists be raised. It was also proposed that the guiding role of the party be increased in all areas of socialist construction, especially in the economic sphere, and the proletarian nucleus of the party be augmented.

The congress adopted a new set of party Rules, and, as a result of the formation of the Soviet Union, the RCP(B) was renamed the ACP(B), or All-Union Communist Party (Bolshevik). Kamenev's report, "On the Immediate Problems of Economic Construction," was removed from the agenda at the suggestion of a number of delegations, since he had demonstrated by his vote against the resolution on the Central Committee's report that his point of view did not correspond to the party line.

The congress approved the "Address to All Members of the Leningrad Organization," in which it gave a political appraisal of the behavior of the organization's delegation to the congress and issued an appeal to Leningrad Communists to put an end to all attempts to subvert party unity. Before it adjourned, the congress sent a group of Communists to Leningrad to explain the party line and to expose the opposition's activities. The Communists of Leningrad condemned the opposition, expressed their support of the congress, and declared that the Leningrad delegation did not express the will of the organization.

The congress elected the membership of the Central Committee of the ACP(B) (63 members and 43 candidate members) and the Central Control Commission (163 members). It scientifically substantiated and enunciated the party's course toward the industrialization of the country. It condemned the attempts of the anti-Leninist elements in the party to revise the general party line, which was oriented toward the victory of socialism. The Fourteenth Congress of the party entered history as the congress of the industrialization of the country.

FOUR-TERMINAL NETWORK, an electrical network or a part of a network with four poles, or terminals, to which other networks or parts of another network may be connected. The four-terminal network is the most widely used type of multiterminal network.

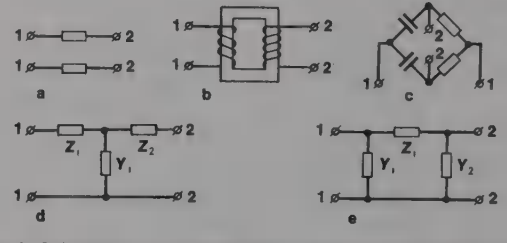

Figure 1. Schematics of four-terminal networks: (a) a power line, (b) ■ transformer, (c) ■ bridge circuit, (d) a four-terminal T network, (e) ■ four-terminal pi network; (1) input terminals, (2) output terminals, (*Z*) impedances of the network elements, (*Y*) admittances of the network elements

In four-terminal networks, two pairs of terminals, called the input terminals and the output terminals, are usually distinguished (Figure 1). The input terminals are used to connect a network to a source of electrical energy; the output terminals, to connect a

network to a load. If the four terminals are grouped in pairs, the network is known as a two-terminal–pair network, which is also called a four-pole, a quadripole, a four-pole network, a quadripole network, or a quadrupole network.

If the relationship between the currents flowing through a four-terminal network and the voltages across the network's terminals is linear, the network is said to be linear; in the opposite case, the network is referred to as nonlinear. The main characteristic of a linear four-terminal network is the complex transfer ratio, which is equal to the ratio of the complex amplitudes at the network's input and output. A four-terminal network is said to be bilateral if its characteristics do not change when the connections to a source and a detector are reversed.

Examples of four-terminal networks include transformers, power lines, bridge circuits, and electric filters. [29–362–3]

FOURTH CONFERENCE OF THE RUSSIAN SOCIAL DEMOCRATIC LABOR PARTY (Third All-Russian Conference of the RSDLP), a conference held from Nov. 5 (18) to Nov. 12 (25), 1907, in Helsinki, Finland. The conference was attended by 27 delegates comprising ten Bolsheviks, four Mensheviks, five Polish Social Democrats, three Latvian Social Democrats, and five Bundists. The delegates represented party organizations in Moscow and St. Petersburg and in the central industrial provinces, the Urals, the Volga Region, Siberia, the Northern Caucasus, Transcaucasia, and southern Russia. V. I. Lenin was among the Bolshevik delegates at the conference.

The agenda of the conference included discussion of three topics: the tactics to be employed by the Social Democratic faction in the State Duma, the faction's local organizations and the improvement of communication between the Central Committee and local organizations, and participation in the bourgeois press.

In his report on the tactics to be used by the Social Democratic deputies in the Duma in response to the onset of reaction, Lenin called on the deputies to point out that the bills sponsored by the government and the liberal-bourgeois elements run counter to the people's interests. He stressed that the Social Democrats should use the Duma not for the legislative "reforms" advocated by the Mensheviks but for the revolutionary education and organization of the proletariat and for large-scale agitation for a democratic republic, confiscation of the lands of the *pomeshchiki* (landowners), and an eight-hour workday. They would be able to accomplish these tasks, Lenin said, if they adhered to an independent political line and did not ally themselves with the Cadets. The Mensheviks and the Bundists continued to insist on the need for "purely practical" work in the Duma and appealed for support of legislative activity in a bloc with the Cadets.

The conference adopted the resolution drafted and proposed by Lenin on behalf of the St. Petersburg all-city conference. The resolution contained the Bolshevik assessment of the Third State Duma and of the policies of the autocracy and set forth the revolutionary tactics to be used in the Duma by the Social Democratic deputies. Agreements with deputies of the Populist parties and with the Trudoviki, who were left of the Cadets, were sanctioned for the purpose of freeing the peasantry from the influence of the liberal bourgeoisie. The conference named the RSDLP delegation in the State Duma the Social Democratic faction, barred Social Democrats from participating in the bourgeois press, and drafted measures for improving communication between the Central Committee of the RSDLP and local party committees.

FOURTH CONGRESS OF SOVIETS OF THE USSR, a congress held in Moscow from Apr. 18 to Apr. 26, 1927. The congress was attended by 1,601 voting delegates and 747 delegates with observer status. Industrial workers made up 47.1 percent of the delegates, peasants, 28.3 percent, and nonindustrial workers, 24.6 percent. Party membership was held by 72.5 percent of the delegates, and 116 of the delegates were women.

The agenda of the congress included the summary report of the government of the USSR, which was delivered by A. I. Rykov. V. V. Kuibyshev reported on the state of industry and the prospects of its development. M. I. Kalinin identified the primary goals of agriculture in terms of the overall development of the economy and the industrialization of the country, and K. E. Voroshilov spoke on the defense of the country and on the Workers' and Peasants' Red Army. Constitutional questions and Central Executive Committee elections were also part of the agenda.

The congress approved the activities of the Soviet government. Kuibyshev noted in his report that overall industrial production had increased by 20 percent in 1926 and 1927 and that the output of the industries responsible for producing the country's means of production had grown by 23 percent. The delegates adopted a resolution enjoining the government to draw up as soon as possible a five-year plan for the economy of the USSR.

Kalinin pointed out in his report that the Soviet state was the first in history to look upon agriculture as part of an integrated national economy. A special section of the report was devoted to the development of kolkhozes and sovkhozes. The congress defined goals for agriculture that were linked with the industrialization of the country.

Voroshilov's report dealt with measures that were needed to increase the defense capability of the USSR. The delegates confirmed the unswerving will of the peoples of the USSR to maintain friendly relations with other states.

Among the amendments to the Constitution of the USSR that were introduced by the congress was an amendment involving proportional representation at the All-Union Congresses of Soviets. It was established that city soviets would send one deputy for every 25,000 voters and that provincial and okrug congresses of soviets would send one deputy for every 125,000 voters. The congress combined two commissariats to form the People's Commissariat of Internal and Foreign Trade of the USSR, and the Central Statistical Board was granted the status of a consolidated people's commissariat of the USSR. The new Central Executive Committee that was elected represented 48 nationalities.

FOURTH REPUBLIC, a bourgeois republic in France that was established in 1944 after the liberation of the country from fascist German occupation and that existed until 1958. The constitution of the Fourth Republic was adopted in 1946. Until the constitution went into effect, the country was governed by a provisional regime (1944–46). In 1958 the Fifth Republic was established in France. [29–349–1]

FOURTH (UNITY) CONGRESS OF THE RUSSIAN SOCIAL DEMOCRATIC LABOR PARTY, a congress held in Stockholm, from Apr. 10 to Apr. 25 (Apr. 23 to May 8), 1906. The congress was attended by 112 voting delegates from 57 organizations of the RSDLP and 22 delegates with observer status. A total of 62 organizations were represented. Of the 12 observers representing national Social Democratic parties, the Social Democracy of the Kingdom of Poland and Lithuania accounted for three, as did both the Latvian Social Democratic Labor Party and the Bund; the Ukrainian, Finnish, and Bulgarian Social Democratic parties each sent one observer. The Bolsheviks had 46 votes, and the Mensheviks 62. In all, 157 persons took part in the work of the congress.

The political situation created by the Revolution of 1905–07 required that the split in the party be mended, since it was disrupting the unity of the working class. Increasingly, attempts at unifying the RSDLP were being made in such places as St. Petersburg, Kharkov, and Baku. Although V. I. Lenin favored the unification, he did not slur over his differences with the Mensheviks on aspects of the revolution: "We agree to uniting the two parts, but we shall never agree to mixing them up" (*Poln. sobr. soch.*, 5th ed., vol. 47, p. 80).

In late 1905 the leaders of the two factions formed a united

Central Committee of the RSDLP for the purpose of convening the congress. In the party organizations, key draft resolutions prepared separately by the Bolsheviks (written by Lenin) and by the Mensheviks were discussed during the election of delegates to the congress. Delegates to the previous congresses had been elected by members of the RSDLP committees; for this congress, they were chosen by general meetings consisting of from one to 300 party members. Many of the organizations in industrial regions—where the Bolsheviks predominated—were seriously weakened by repression and either were unable to send delegates or sent fewer than they were allowed. The makeup of the congress, therefore, did not reflect the actual alignment of forces within the party.

The first point on the agenda of the congress was a review of the agrarian program; Lenin, P. P. Maslov, G. V. Plekhanov, S. A. Suvorov, and P. P. Rumiantsev spoke on this topic. The second point—the immediate situation and the class goals of the proletariat—was the subject of speeches by Lenin and A. S. Martynov. P. B. Aksel'rod and Lenin addressed the congress on the third point—the tactics to be used regarding election results in the State Duma and regarding the Duma itself. The fourth point—the question of an armed uprising—was dealt with by V. P. Makhnovets, L. B. Krasin, and F. A. Lipkin. Also on the agenda were elections, routine reports, and a number of issues resolved by special commissions without floor discussion. These issues included partisan actions, a provisional revolutionary government and revolutionary self-government, trade unions, the peasant movement, parties and organizations other than the Social Democrats, party organization, and union with the Social Democracy of the Kingdom of Poland and Lithuania, the Latvian Social Democratic Labor Party, and the Bund. Two items of the agenda were removed from discussion entirely—the issue of the soviets of workers' deputies and, in connection with the nationalities question in the party program, the issue of a special constituent assembly for Poland. In addition to reports on the agrarian question and on the immediate situation, the texts of which have been lost, Lenin delivered speeches on the state Duma and on such issues as the armed uprising.

The congress began its work with a review of the party's agrarian program, since the agrarian question formed the basis of the first Russian revolution and had determined the revolution's national characteristics. The course of the revolution had demonstrated the inadequacy of the agrarian program adopted in 1903 by the Second Congress of the RSDLP: opposed to all landholding by the *pomeshchiki* (landowners), the peasantry sought to acquire not simply the *otrezki*, or lands lost by them as a result of the abolition of serfdom, but all the lands held by the *pomeshchiki*.

Lenin viewed the agrarian program of Bolshevism both as a proletarian program in a peasant revolution directed against the vestiges of serfdom and as a program of a peasant uprising. The program was drafted for the purpose of creating between the working class and the peasantry an alliance that would achieve the goals of the bourgeois democratic revolution and would transform it into a socialist revolution. Although Lenin's report on the issue was not preserved, it is known that he defended and developed the point of view that he set forth in the pamphlet *Revision of the Agrarian Program of the Workers' Party*, which came out on the eve of the congress and was distributed to the delegates.

Lenin's program aimed at a revolutionary break with all landholding of the past. Its main points were (1) the confiscation of all church, monastery, appanage, state, and cabinet lands and all lands of the *pomeshchiki*; (2) the establishment of elected peasant committees for eliminating all traces of the power and privileges of the *pomeshchiki* and for redistributing the confiscated land; and (3) the nationalization of all land after the achievement of certain political conditions, that is, after the final victory of the revolution and the establishment of a democratic republic. The program reflected the scope and depth of the agrarian movement that was unfolding in Russia. It called the peasants to revolutionary action and was linked with the general tactical line of the Bolsheviks of transforming the bourgeois democratic revolution into a socialist one.

A group of Bolsheviks that included Suvorov, V. A. Bazarov, and J. V. Stalin and that came to be known as the *razdelisty* (partitionists) advocated dividing the lands of the *pomeshchiki* and transferring the ownership to the peasants. Although the program of the *razdelisty* was erroneous, it bore a revolutionary-democratic character. Assuming a long interval between the bourgeois democratic revolution and the socialist revolution, the *razdelisty* failed to see that nationalization of the land would expedite the growth of the democratic revolution into a socialist revolution.

The Mensheviks advocated a program of municipalization of land; that is, the lands of the *pomeshchiki* were to be transferred to local bodies of self-government such as *zemstvos*, which would in turn lease the lands to the peasants. This reformist solution of the agrarian problem failed to bring the peasantry into the revolution. Although the Menshevik program was adopted by the congress by a majority vote, a number of amendments were introduced at the insistence of the Bolsheviks, one of which was a demand for the confiscation of the lands held by the *pomeshchiki*. Lenin called this program "a deal with reaction" (*ibid.*, vol. 13, p. 20).

Differences with the Mensheviks became even sharper during an evaluation of the immediate situation and the discussion of the state Duma. The Mensheviks openly challenged the hegemony of the proletariat in the revolution, praised the role of the Duma as a national political center, and in effect rejected an armed uprising. Lenin pointed out that the essence of a revolution is the direct revolutionary struggle of the masses and not constitutional, legal forms of action. He proposed that the Duma and its conflicts with the government be used to deepen the revolutionary crisis. The congress adopted the Menshevik resolution relegating the proletariat to a position of support of the Cadet Duma. Its resolution on an armed uprising was a veiled criticism of the December uprising and did not address the need for renewed insurgence.

The congress accepted the Social Democracy of the Kingdom of Poland and Lithuania into the RSDLP and worked out conditions for a union with the Latvian Social Democratic Labor Party and the Bund, which would function as territorial organizations operating among the proletariat of all the nationalities in their own regions. Fearing they would alienate the workers, the Mensheviks were forced to accept Lenin's formulation of the first paragraph of the party Rules for party membership. The Central Committee that was elected by the congress consisted of three Bolsheviks and seven Mensheviks, and only Mensheviks were elected to the editorial board of the party's central organ.

The union with the Mensheviks that was effected at the congress was merely a nominal union, since ideological differences remained. The important, practical business of the congress—the fusion of the RSDLP with national Social Democratic parties—was partially accomplished. Rallying the revolutionary forces of the working class around the principles of proletarian internationalism facilitated the struggle against tsarism. After the congress, the Bolshevik delegates approved an address written by Lenin to the party, in which he stated that the Bolsheviks would support the decisions of the congress but would wage an ideological struggle against the decisions they considered erroneous.

FOUR-YEAR SEJM, the parliament of the Polish-Lithuanian Commonwealth (Rzeczpospolita) from 1788 to 1792.

The Four-year Sejm carried out many reforms of the state

structure. Through the efforts of the "patriotic party," which had formed under the ideological leadership of H. Kołłontaj and S. Staszic, it voted to expand the Polish Army to 100,000 men (October 1788), abolished the Permanent Council (January 1789), and passed a law on cities (April 1791). The reforms adopted by the Four-year Sejm were summarized in the Constitution of May 3, 1791.

Reactionary magnates opposed to the constitution formed the Confederation of Targowica in 1792, which invited Russia and Prussia to occupy the commonwealth. The reforms adopted by the Four-year Sejm were rescinded, and a new Sejm was convened in Grodno in 1793 and compelled to ratify the second partition of the country.

FRAME FREQUENCY. (1) The rate of succession of the film frames during motion-picture filming or projection; the same as the filming or projection speed. The standard filming and projection speed is 24 frames per sec; 8-mm and 16-mm films are sometimes exposed and projected at a speed of 16 frames per sec. If filming is done at a speed higher or lower than the projection speed, the action photographed will be seen as retarded or speeded up, respectively, during projection. The two effects are widely used in all types of motion pictures.

(2) The rate at which complete frames change on the screen of a television receiver. The frame frequency adopted as a television standard in the USSR is 25 frames per sec. [29–84–2]

FRAZIL ICE, an accumulation of loose, spongy ice within a body of water (deep frazil ice) or on its surface (surface frazil ice). Frazil ice forms from tiny crystals of deep ice (intermediate and bottom ice) and from grease ice and slush. It occurs before the freeze-up when water is supercooled below 0°C, primarily on mountain rivers and rivers with rapids, below polynyas and the lower pools of hydroengineering complexes, and, occasionally, on lowland rivers and lakes.

Frazil ice, carried downstream by the current, covers large areas and dams up the channel, causing ice jams. It also considerably impedes the operation of hydroengineering structures by clogging up the filters of water intakes and the aperture grills at hydroelectrical power plants. [29–1521–1]

FREQUENCY. The frequency of an event A is the ratio m/n of the number m of occurrences of A in a given series of trials to the total number n of trials. If the trials are independent and there is a definite probability p of the occurrence of A in an individual trial, then, for arbitrarily small $\epsilon > 0$, at sufficiently large m it is practically certain that the frequency m/n satisfies the inequality

$$\left|\frac{m}{n} - p\right| \leq \epsilon$$

(*see* LARGE NUMBERS, LAW OF and PROBABILITY).

The term "frequency" is used in mathematical statistics to designate the number of elements of a set that have a specified attribute. [29–84–1]

FREQUENCY, ELECTRICAL, the time parameter of a periodically (cyclically) varying electric current, expressed by the ratio of the number of complete cycles of current variation to unit of time; the quantity is the inverse of the period of current variation. It is measured in hertz (Hz). For a sinusoidal alternating current the concept of angular frequency is used, which is related to the electrical frequency by the formula $\omega = 2\pi f$ (where ω is the angular frequency and f is the electrical frequency).

In many countries of the world, including the USSR, the frequency of the current generated by electric power stations and commercially distributed to industry is 50 Hz; in the USA it is 60 Hz. Railroads in many countries use current with a frequency of 16⅔ Hz (for electric traction) as well as frequencies of 25 and 75 Hz (for automatic block signaling, for example, on track circuits). In aviation, the current used has a frequency of 400 Hz (for independent power-supply systems). In certain industrial and agricultural equipment the operating frequency is raised to 200–400 Hz. [29–85–2]

FREQUENCY-CONTRAST RESPONSE CURVE, a function with which the sharpness characteristics of optical imaging systems and of the individual elements of such systems are evaluated. It is the Fourier transform of the line scattering function, which describes the nature of the blurring of an image of one thin line taken separately. It gives more complete information about the properties of an imaging system than does the resolving power because it characterizes the ability of the system to transfer adequately to the image details of any size from an object, and not merely the smallest.

Use of the frequency-contrast response curve has been of particular value in the development of aerial photographic surveying, space photography, and other specialized techniques of optical imaging. Since the 1970's a variety of equipment has been produced industrially in several countries for the measurement of the frequency-contrast response curve of objective lenses and photosensitive emulsions. Computer programs have been used extensively to calculate frequency-contrast response curves, and theoretical studies have also been conducted.

FREQUENCY DICTIONARY, a type of dictionary, usually monolingual, in which lexical units are characterized according to their frequency of use in a corpus of texts that are representative of the language as a whole, of a particular style, or of an individual author. Such dictionaries are classified according to the type of lexical unit examined as word-form, word (lexeme), stem (used in information science), semantic (words with particular meanings), and word-group frequency dictionaries.

Absolute and relative characteristics of the use of a lexical unit x are distinguished. An absolute characteristic is the frequency f of a given lexical unit x equal to the number of uses of x in the investigated corpus of texts $f(x)$. A frequency dictionary has either $f(x)$ or the normalized frequency $f(x)/N$, where N is the number of examined words in the text. The relative characteristic of the use of a lexical unit is either the unit's rank, which is the number of lexical units in the dictionary with an absolute characteristic of use greater than or equal to that of the given lexical unit, or some property that permits the rank to be calculated more or less accurately. Most frequency dictionaries give both absolute and relative characteristics.

Frequency dictionaries are used in the development of efficient methods of teaching language. They are used in information science to isolate key words and in communication theory to create efficient codes.

FREQUENCY-INDEPENDENT ANTENNA, an antenna with primary electrical characteristics that vary insignificantly with frequency over an extremely wide range; the various types of such antennas constitute a group of broadband antennas for which the ratio of maximum operating frequency to minimum range to 20:1 or more. The theoretical and technological foundations for frequency-independent antennas were established between 1957 and 1965 by the American scientists V. H. Rumsey, D. Dyson, and others.

The weak dependence of the antennas' characteristics (the shape of the directive pattern, the front-to-rear ratio, the input impedance, and so on) on frequency stems from the fact that the radiation field is created by currents distributed over a finite portion of the antenna surface, known as the active region, beyond whose limits the currents decrease sharply; as the frequency varies, the active region changes in such a way that its relative dimensions expressed in terms of the wavelength λ corresponding to the frequency remain unchanged. The lower wavelength limit λ_{max} of the antenna's operating range is determined by the frequency at which the active region is shifted to the edge of the antenna. The antenna's operating range can, in principle, be extended toward the shorter wavelengths as far as desired, but in practice the limit is determined by a number of incidental factors, such as the cross-sectional dimensions of the power feeder that are acceptable for given values of the losses introduced, the breakdown voltage, the transmitted power, and so on.

The most common frequency-independent antennas are in the form of two-arm spiral and conical helical antennas, log-periodic antennas, and sickle-shaped dipoles. There are also multiarm spiral and helical antennas that have several independent inputs; a well-known type is in the form of a conical dipole with an ultrawide range of input impedances.

Frequency-independent antennas are used for shortwave radio communications, telemetry, and radio astronomy. During the 1970's lightweight types of relatively simple design were developed for various frequency ranges: log-periodic wire antennas were developed for decameter waves, and spiral and helical antennas were created for centimeter and millimeter waves from strip conductors deposited on a fiberglass substrate by a photochemical process. Highly directional frequency-independent antennas are being designed as horn antennas with walls having transverse ribs and antenna arrays composed of log-periodic or conical helical radiators positioned along radii in a specific sector of a circle.

FREQUENCY METER, an instrument for measuring the frequency of periodic processes (oscillations). The frequency of mechanical vibrations is usually measured by means of mechanical vibration frequency meters and by electrical meters equipped with transducers to convert the mechanical vibrations into electrical oscillations.

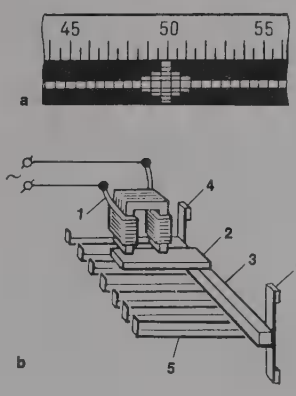

Figure 1. Electromechanical vibration frequency meter: (a) scale, registering ■ reading of 50 Hz, (b) diagram of the instrument; (1) electromagnet winding, (2) electromagnet armature, (3) base of the frequency meter, (4) elastic supports, (5) reeds

The simplest mechanical vibration frequency meter operates on the resonance principle and consists of a series of flexible reeds fastened at one end to a common base. The lengths and masses of the reeds are chosen in such a way that their natural vibration frequencies form a specified discrete scale, from which the value of the frequency being measured is determined. When mechanical vibrations act on the base of the meter, they cause the flexible reeds to vibrate; the highest vibration amplitude is observed on the reed whose natural vibration frequency is equal or close to the value of the frequency being measured.

The frequency of electrical oscillations is measured by means of electromechanical, electrodynamic, electronic, moving-iron, and moving-coil frequency meters. The simplest electromechanical type consists of an electromagnet and a series of flexible reeds (as in the mechanical frequency meter) on a common base that is attached to the armature of the electromagnet (Figure 1). The electrical oscillations being measured are fed to the winding of the electromagnet; the armature vibrations thereby produced are transmitted to the reeds, and the value of the frequency being measured is determined from the vibrations.

The principal element in electrodynamic frequency meters is a ratio meter with an oscillatory circuit in one of its branches that is permanently tuned to the average frequency for the measurement range of the given instrument (Figure 2). When connected to an AC circuit, the moving part of the ratio meter is deflected by an angle proportional to the phase shift between the currents in the windings of the ratio meter, which depends on the ratio of the frequency being measured to the resonance frequency of the oscillatory circuit. The measurement error of electrodynamic frequency meters ranges from 10^{-1} to 5×10^{-2}.

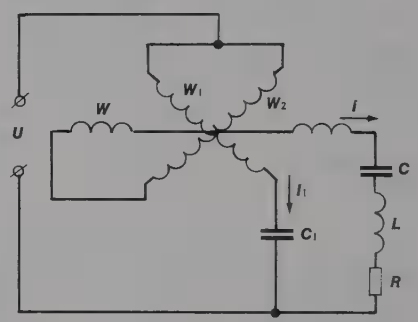

Figure 2. Schematic diagram of an electrodynamic frequency meter: (*W*) fixed coil of a ratio meter consisting of two identical parts, designed to create a uniform magnetic field; (W_1) and (W_2) moving coils rigidly secured together at an angle of 90°, which interact with coil *W*; (*C*), (*L*), and (*R*) electrical capacitance, inductance, and resistance, respectively, of the oscillatory circuit; (C_1) capacitor to produce a phase shift of 90° between *U* and I_1; (*U*) voltage whose frequency is being measured; (*I*) and (I_1) currents in the branches of the ratio meter

The frequency of electromagnetic oscillations in the radio-frequency and microwave-frequency ranges is measured by means of electronic frequency meters (wavemeters), such as the resonant, heterodyne, and digital types.

The operation of a resonant-type frequency meter is based on the comparison of the frequency being measured with the frequency of natural oscillations in an electrical circuit (or a microwave resonator) that is tuned to resonance with the frequency being measured. The meter consists of an oscillatory circuit with a coupling loop that picks up the electromagnetic oscillations (radio waves), a detector, an amplifier, and a resonance indicator (Figure 3). During measurement, the circuit is tuned by means of a calibrated capacitor (or the plunger of a microwave resonator) to the frequency of the electromagnetic oscillations being picked up until resonance is achieved, as shown by the greatest deflection of the pointer on the indicator. The measurement error ranges from 5×10^{-3} to 5×10^{-4}.

In heterodyne frequency meters, the frequency being measured is compared with a known frequency (or one of its harmonics) produced by an oscillator, or heterodyne. As the heterodyne frequency is tuned to the frequency of the oscillations being mea-

sured, beats occur at the output of a mixer (in which the frequencies are compared); after amplification the beats are indicated by the pointer on an instrument, by an earphone, or sometimes by an oscilloscope. The relative error of heterodyne frequency meters ranges from 5×10^{-4} to 5×10^{-6}.

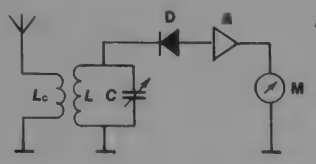

Figure 3. Schematic diagram of a resonant-type frequency meter: (L_c) coupling loop, (L) and (C) oscillatory circuit (C is a calibrated variable capacitor), (D) detector (semiconductor diode), (A) amplifier, (M) indicator (microammeter or millivoltmeter)

Digital frequency meters (frequency counters) are now widely used. Their operation involves a count of the number of periods in the oscillations being measured during a specified time interval. Frequency counters consist of a device that converts the sinusoidal voltage of the frequency being measured into a train of unidirectional pulses, a gate for the pulses that opens for a certain time interval (usually from 10^{-4} to 10 sec), an electronic counter that registers the number of pulses at the gate output, and a digital display. Modern digital frequency counters operate over a frequency range from 10^{-4} to 10^{9} hertz with a relative measurement error from 10^{-9} to 10^{-11} and a sensitivity of 10^{-2} volt. Such devices are used primarily for testing radio equipment and, with various measuring transducers, for measuring temperature, vibrations, pressure, strain, and other physical quantities.

Primary and secondary frequency standards, which have an error in the range from 10^{-12} to 5×10^{-14}, function as a type of high-accuracy reference frequency meters. The rotational speed of shafts in machines and mechanisms is measured with a tachometer.

FREQUENCY MODULATION, a method of modulating oscillations, in which the frequency of the high-frequency carrier oscillations is varied over time according to a law that corresponds to the signal being transmitted. A feature of frequency modulation is its high immunity to noise. Frequency modulation is used for high-quality transmission of information: in radio broadcasting (in the very-high-frequency band), for the audio signal of television programs, in voice-frequency telegraphy, in radiotelephone communications, and in other fields. [29–85–3]

FREQUENCY-RESPONSE METHOD, in automatic control theory, a method of evaluating the dynamic characteristics of an automatic control system by using the system's frequency-response curves expressed as the steady-state response of the system to a harmonic input signal.

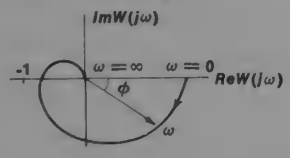

Figure 1. Amplitude-phase characteristic of an open-loop system

The steady-state response of a stationary linear system to an input signal $x_1 = A_1 e^{j\omega t}$ is also a harmonic signal $x_2 = A_2 e^{j(\omega t + \phi)}$. The output and input signals are related by the complex transfer function $x_2 = W(j\omega)x_1$, for which the modulus is given as the ratio of the signal amplitudes $|W(j\omega)| = A_2/A_1$ and the argument $W(j\omega)$ is given as the phase shift $\phi(\omega)$ between x_2 and x_1. The hodograph of $W(j\omega)$ on the complex plane as ω varies from 0 to $+\infty$ (Figure 1) is called the amplitude-phase characteristic (APC). Every point on the hodograph corresponds to a specific frequency. The length of the vector drawn from the origin of coordinates to a point on the APC corresponding to a frequency ω is equal to $|W(j\omega)|$, and the phase shift of the vector relative to the real, positive semiaxis is the argument of $W(j\omega)$. The dependence of the modulus and the argument on frequency is expressed by the amplitude-frequency characteristic (AFC) and phase-frequency characteristic (PFC). When the logarithmic amplitude-frequency characteristic (LAFC) and the logarithmic phase-frequency characteristic (LPFC) are plotted, the frequency is laid out along the axis of abscissas on a logarithmic scale, and on the axis of ordinates the values of the modulus expressed in decibels $|W(j\omega)|$ dB (for LAFC) and of the argument $\phi(\omega)$ (for LPFC) are laid out on a linear scale (Figure 2). The frequency-response curves are plotted according to the complex transfer function derived from the system's differential equation or according to the results of measurements of the amplitude ratio and the phase shift between signals at various frequencies. The frequency-response curves (APC or LAFC and LPFC) are used to examine the stability of an automatic control system and the quality indexes of transients in the system. The frequency-response method was introduced into automatic control theory by A. V. Mikhailov between 1936 and 1938.

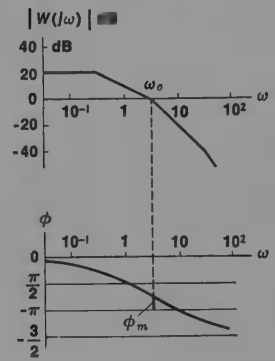

Figure 2. Logarithmic amplitude-frequency and phase-frequency characteristics of an open-loop system

Use of the Nyquist criterion makes it possible to determine beforehand the stability of a closed-loop linear system (that is, a system with feedback) from the APC of the open-loop system; a closed-loop system is stable if the APC of the open-loop system does not enclose the critical point having the coordinates $-1, 0$ (Figure 1). The stability of the closed-loop system can be evaluated directly from the LAFC and the LPFC of the open-loop system; the closed-loop system is stable if the phase margin $\phi_m = \pi - |\phi(\omega)_c|$ is positive (Figure 2; ω_c is the cutoff frequency at which LAFC intersects the axis of abscissas). The cutoff frequency can be used as a measure of the system's speed of operation, and the phase margin is useful as a measure of the rate of decay of free oscillations in the system. Logarithmic frequency-response curves and the Nyquist criterion have been used as a basis for developing very effective methods of synthesizing correction devices that ensure the required dynamic characteristics for a closed-loop system. Similar frequency-response methods have been devised for the analysis and synthesis of linear pulse systems. The quality indexes for a transient in a linear system are evaluated with respect to the transient response, which expresses the response of a system to a step signal. The Soviet scientist V. V. Solodovnikov has proposed methods for the synthesis and evaluation of the properties of transient response with respect to the real frequency-response curve $P(\omega) = ReW(j\omega)$. For nonlinear closed systems the Soviet scientist L. S. Gold'farb has used the frequency-response method to derive a criterion for the occurrence and stability of self-excited oscillations, and the Rumanian mathematician V.-M. Popov has proposed a criterion for absolute stability.

E. L. L'vov [29–87–1]

FREQUENCY-SHIFT TELEGRAPHY, a method of transmitting electric telegraph signals over communications lines by means of alternating currents. It converts DC signals formed by telegraph apparatus into AC signals, which are then transmitted over the line (cable, radio-relay link, or the like). The channel equipment (*see* MULTICHANNEL COMMUNICATION) produces from one to 24 or more channels within one standard voice-frequency telegraph channel (0.3–3.4 kilohertz). The signal in each channel of the system is transmitted on its own carrier frequency, usually by means of frequency modulation; amplitude and phase modulation are also sometimes used. [29–86–1]

FREQUENCY STANDARD, PRIMARY (Russian, *etalon chastoty*), a frequency measure that reproduces a unit of frequency with the greatest accuracy achievable at the time. It differs from a secondary frequency standard (*standart chastoty*) in that the error has been more closely studied and its use is more strictly regulated. (*See* QUANTUM FREQUENCY STANDARDS.) [29–92–2]

FREQUENCY STANDARD, SECONDARY (Russian, *standart chastoty*), a device containing a reference frequency that emits an electric signal with a fixed frequency or a range of fixed frequencies. (*See* QUANTUM FREQUENCY STANDARDS and QUANTUM CLOCK.) [29–92–1]

GABLE (Russian, *shchipets*), in architecture, the upper portion of (usually) an end wall of a building, bounded by the two slopes of the roof and not separated on the bottom by a cornice (unlike a pediment). The term is sometimes applied to structures with a steep, two-sided roof that forms a gable with an acute angle; such structures sometimes surmount the main facade of a building. The Russian term *vimperg* is also sometimes used to mean a gable. [29–1604–1]

GAGE (Russian, *shablon*), in engineering, a device or tool for checking the accuracy of the shape of various finished items; a standard to which uniform items are manufactured.

A radius gage is an instrument for checking the profile radii of curvature of convex and concave surfaces of machine parts and other items. It is a steel plate 0.5–1 mm in thickness with a convex or concave curvature at the end. The circular radii are from 1 to 25 mm. The gage is positioned next to the item in order to check the radius of curvature. Any deviation from the radius of curvature of the gage is judged by the gap.

A thread gage is a device for determining thread pitch and angle. It consists of a steel plate 0.5–1 mm thick with teeth designed to fit the axial profile of a thread. There are gages for checking threads in inches and in the metric system. The gage is placed against the thread to be checked in such a way that the gage teeth enter the depressions in the thread. The correspondence of the pitch and angle of the thread to those of the gage is determined by the gap or by the tightness of fit. M. N. SOSNENKO [29–792–1]

GALLERY (Russian, *shtrek*), a horizontal, underground mine passage that has no exit on the surface and that usually follows the vein or rock in which it is excavated, in which case it may be called a drift or rock drift. Various types of galleries are distinguished according to purpose, including primary (main roads), panel, horizontal, excavation, intermediate, transport, and ventilation galleries. [29–1494–4]

GALLNUT, a gall formed on young branches and leaves of certain species of oak and sumac. Gallnuts form at the sites where the larvae of gall wasps or aphids develop. They are spherical or somewhat elongated excrescences measuring 1.5–2 cm or more in diameter. Gallnuts contain tannins (up to 70 percent of the dry mass), which are used for tanning leather and making pharmaceuticals (for example, astringents). [29–250–3]

GARLIC (*Allium sativum*), a bulbous plant of the family Liliaceae. The erect or drooping leaves are flat, lanceolate, and grooved. The flower stalk, which is developed and straight, measures 60–150 cm in height. The bulb is compound and consists of two to 50 cloves, each of which is covered with a coarse, leathery scale.

Garlic grows wild in the mountains of Middle Asia, southern Kazakhstan, the Caucasus, India, and the Mediterranean region. It is cultivated in Europe, Asia, North and South America, and tropical Africa and Australia. In the USSR garlic is almost ubiquitous.

Cultivated garlic has bolting and common, or nonbolting, forms. There is an intermediate form with attenuated bolting. Garlic is classified as spring or winter, according to the method of cultivation. Spring garlic has narrow leaves and does not usually bolt; winter garlic has broad leaves and may be bolting or nonbolting. Winter garlic gives considerably higher yields than spring garlic but is not suitable for prolonged storage. Spring garlic can be preserved until the next harvest. In contrast to wild garlic, cultivated garlic does not yield seeds but forms 60 to 450 aerial bulbels in the inflorescence and approximately the same number of flower buds, which wither before they open. If the bulbel is not used for propagation, the flower stalks are broken off soon after they appear from the axil of the last leaf, increasing the harvest of underground bulbs by 20 to 40 percent.

Garlic is used in cooking in fresh and preserved form. The bulbs contain 35–42 percent dry matter, 6.0–7.9 percent protein substances, 7.0 to 28 mg percent vitamin C (the leaves contain up to 80 mg percent), 0.5 percent sugars, and 20–27 percent polysaccharides. The pungent flavor and distinctive odor of garlic are caused by the presence of essential oil (0.23–0.74 percent) containing phytoncides that kill the causative agents of many diseases.

Phytoncidal preparations of garlic bulbs—garlic tincture and *allilsat* (a 40-percent alcoholic garlic extract)—are used medicinally to intensify the motor and secretory functions of the gastrointestinal tract. They are prescribed internally to suppress the processes of putrefaction and fermentation in the intestine in cases of atonia of the intestine and in colitis, as well as in cases of hypertension and atherosclerosis.

About 20 selectively bred varieties have been regionalized in the USSR. Cultivated garlic is propagated by cloves of root bulbs or by aerial bulbels. In the first year single-cloved bulbs are grown from the bulbels; the next year bulbs divided into cloves appear. Spring garlic is set out in early spring; winter garlic is planted in time to take root before prolonged frosts. About 400,000 cloves are set out per hectare (500–2500 kg/ha). Plantings consist of single-, double-, or triple-row strips, with 20 or 40 cm between rows. Where there is excessive moisture, garlic is grown on ridges or in beds. The average yield is 50–80 quintals per ha. The most dangerous pest of garlic is the stem eelworm (*Ditylenchus dipsaci*).

IU. V. ABRAKHINA [29–339–3]

GATE (Russian, *shiber*), a closing device in the form of a slide or damper, used to open or close a channel for the flow of liquids or gases. Gates include draft-regulating dampers in the flues of industrial furnaces and boiler installations as well as sluice gates designed to shut off water-intake channels from a river or to close connections between channels. The working member of a sliding-vane pump is also a type of gate. Small gates are operated manually; large gates are operated by toothed racks, worm drives, and the like. [29–1173–3]

GEAR PUMP, a rotary pump with gears as working members. Involute straight-cut, helical, or herringbone gears are ordinarily used. Such pumps are simple in design, compact, and reliable. Their output ranges from 0.25 to 40 cu m per hr at pressures up to 3 meganewtons per m^2 (30 kg-force per cm^2). Gear pumps are used mainly for circulating petroleum products in machine lubrication systems and in hydraulic drive mechanisms. [29–1156–1]

GENGHIS KHAN (personal name, Temujin). Born circa 1155, in the district of Deliun-Boldok, on the Onon River; died Aug. 25, 1227. Military leader and founder of the unified Mongol empire.

Genghis Khan was the son of Yesugei, a member of the royal Borjigin clan. By 1204 he had eliminated his principal rivals and, having seized vast territories, became the de facto ruler of the many clan-tribal alliances in the subjugated regions. In 1206, at a *khurultai* (assembly) of the steppe aristocracy, he was proclaimed the great khan of all the tribes and was given the title Genghis, from the Turkic *tengis* (ocean, sea).

In domestic policy, Genghis Khan concentrated on uniting the Mongol tribes and centralizing the government of the newly created state in the interests of the feudalized clan-tribal aristocracy. In 1206 he promulgated decrees that constituted a codification of customary law (*yasa*). He divided the Mongol tribes into military-administrative units called thousands: at the command of the khan each unit had to produce 1,000 mounted soldiers. The thousands, along with pasturelands, were granted as fiefs (*khubi*) to his relatives and to the *noions*—members of a new class of feudal lords made up of his trusted lieutenants. Genghis Khan created a personal guard (*keshig*) of 10,000 men that served as the principal force in the suppression of any stirrings of discontent in the empire.

In foreign policy, Genghis Khan sought to extend the territory under his control as far as possible. His strategy and tactics were based on thorough reconnaissance and sudden attack; his troops tried to divide the enemy forces and set up ambushes using special detachments to lure the enemy. He also made use of large groups of cavalry that could maneuver quickly.

Genghis Khan subdued the peoples of Siberia and eastern Turkestan between 1207 and 1211 and attacked the Jurchen kingdom of Chin in 1211 (*see* MONGOL CONQUESTS OF THE 13TH CENTURY). These wars, waged in the interests of the *noion* class, wreaked havoc on the peoples of the subjugated countries, most of which had achieved a higher level of economic and cultural development than the Mongol tribes, and hampered the development of the Mongol empire itself and the broad masses of its people—the simple *arats* (herdsmen bound to the land). The wars exhausted the empire and led to its political, economic, and cultural decline by the end of the 13th century. Genghis Khan died in the Tangut state of Hsi Hsia during a campaign undertaken in 1226.

N. TS. MUNKUEV [29–604–4]

GLOBULAR CLUSTER, a tightly packed group of stars that can be seen in a small section of the sky, consisting of stars that are close to one another in space and characterized by the spherical shape of the distribution of the stars. Two of the globular clusters closest to us, with a myriad of stars, are located in the constellations Hercules and Centaurus. (*See* STAR CLUSTER.) [29–866–4]

GNATHOSTOMATA, higher vertebrates having jaws, paired nostrils, and paired limbs. The Gnathostomata include fish, amphibians, reptiles, birds, and mammals. [29–157–1]

GOLDFINCH (*Carduelis carduelis*), a bird of the family Fringillidae of the order Passeriformes. The body length is 12 cm. The wings are black with a yellow stripe, and the crown is black or gray. There is a red ring around the beak. The goldfinch occurs in Europe, Western Asia, and Northwest Africa. In the USSR it is found from the western border east to the Enisei River. The goldfinch settles in deciduous groves, felled areas, and gardens. It nests in shrubs or trees. A clutch contains four to six eggs, which are incubated for 12 or 13 days by the female. The bird feeds on seeds of broad bean sorrel, burdock, thistle, and other weeds. The nestlings are fed insects. Goldfinches are frequently kept as pets. [29–1576–4]

GRINDING. (1) In metalworking, the machining of surfaces of workpieces with an abrasive tool. It is performed on grinding machines and other types of meal-cutting machine tools by means of special attachments (such as grinding heads), as well as by hand. A distinction is made between grinding in which the peripheral speed of the tool is approximately 20 m/sec and high-speed grinding, in which the peripheral speed is greater than 50 m/sec. Grinding makes it possible to fabricate metal parts having a precision of class 1 and a surface roughness of class 10. It is widely used to machine external and internal flat, cylindrical, conical, and irregularly shaped surfaces of workpieces made from metals, plastics, ceramics, ferrites, stone, and wood. Rough grinding is also used to some extent to remove large machining allowances from cast pig iron and steel workpieces.

The various types of grinding include external and internal cylindrical grinding, grinding with a planetary motion, external and internal centerless grinding, surface grinding, and grinding of special shapes.

Electrochemical grinding is used to work metals that are difficult to machine. Current-conducting grinding wheels are fed with a DC current, and an electrolyte is supplied to the cutting zone. Grinding can also be performed by means of vibration machining with an abrasive powder suspended in a liquid.

A carborundum abrasive tool is usually used to grind stone. The process may be accomplished by grinders or by hand.

(2) In groats production, grinding removes the germ and the outer parts of the kernel, thereby imparting a definite shape and uniformity to the crushed grains.

A. A. SHISHKIN [29–1298–1]

GRINDING HEAD, an attachment that makes it possible to grind workpieces on metal-cutting machine tools. Located within the housing of a grinding head is a spindle running on roller or gas bearings with a grinding wheel attached to the front section; the rear section of the spindle is rotated by means of a belt drive from an electric or compressed-air motor or from a spindle of the machine tool. Grinding heads can be mounted on lathes for external and internal grinding, on standard planers and planer-type milling machines for grinding long surfaces, and on surface and internal grinding machines for grinding holes greater than 30 mm in diameter. [29–1295–3]

GRINDING MACHINE, in metalworking, a machine tool designed to remove material from workpieces by means of an abrasive tool. The first modern grinding machine (a universal cylindrical grinder) was built in 1874 in the USA. Initially, grinding machines operated with disks, or grinding wheels, made from solid pieces of natural abrasive rocks; stronger wheels of pulverized natural abrasives later came into use. The invention in 1893 of a method of making artificial abrasives (carborundum) substantially broadened the application of grinding machines.

According to the classification adopted for metalcutting machine tools, grinding machines are divided into cylindrical and internal grinding types (including centerless grinders and those with planetary motion), specialized grinders, surface grinders, and other types that operate with an abrasive tool (gear grinders and thread grinders belong to the gear-cutting and thread-cutting group of machines). The characteristics of the tool used impose some added requirements on design and structural materials: resistance to vibration, wear resistance, and the rapid removal of abrasive dust. The principal motion of a grinding machine (*see* METALCUTTING MACHINE TOOL) is the rotation of the abrasive tool at a velocity that is generally considerably higher than the feed rate and other motions.

Cylindrical grinding machines are the most common type. In such machines the workpiece is carried on centers or in a chuck (Figure 1,a) and rotated in a direction opposite to that of the grinding wheel; together with the table of the machine, the workpiece executes reciprocating motion. At the completion of every single (or double) traverse of the table, the grinding wheel is shifted transversely by an amount equal to the cutting depth (*see* MACHINING). External cylindrical and conical surfaces and the ends of workpieces are usually ground on cylindrical grinding machines. Infeed, or plunge, grinding is used to grind external cylindrical, conical, and irregularly shaped surfaces with a wide wheel (wider than the dimension of the workpiece); in this case there is no longitudinal feed.

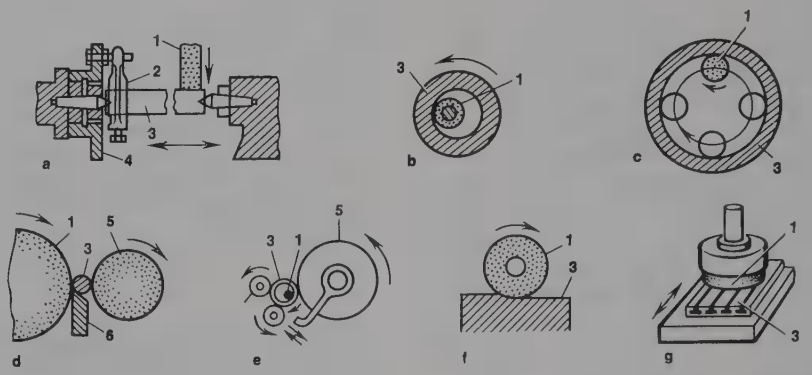

Figure 1. Diagrams of the operation of grinding machines: (a) cylindrical grinder, (b) internal grinder, (c) internal grinder with planetary motion, (d) centerless grinder, (e) centerless internal grinder, (f) surface grinder using the periphery of the wheel, (g) surface grinder using the end of the wheel; (1) grinding wheel, (2) clamp, (3) workpiece, (4) chuck, (5) regulating wheel, (6) workrest blade

Internal grinding machines are designed to grind internal surfaces of rotation. In the most common types the workpiece is rotated around the axis of the hole being ground while the grinding wheel rotates around its own axis (Figure 1,b); the wheel is moved both longitudinally and transversely. Internal grinding machines with planetary motion are used to machine holes in workpieces that are difficult to rotate. In such machines the grinding wheel simultaneously rotates around its own axis and around the axis of the hole being machined (Figure 1,c).

Centerless grinding machines are designed to grind external and internal cylindrical surfaces. When external surfaces are to be ground, the workpiece (or a series of workpieces placed end to end) is positioned between two wheels, one of which is for machining and the other for regulating (Figure 1,d), and is pressed against a workrest blade. As a result of the tilt of the regulating wheel, the frictional forces not only cause the workpiece to rotate but also to feed through. The regulating wheel is also fed transversely. When internal surfaces are to be ground, such as ball bearing races, the workpieces are supported between two pressure rolls and a regulating wheel (Figure 1,e) that rotates the workpiece. The grinding wheel is moved along and across the axis of the hole, if necessary, or only radially (for infeed grinding). Centerless grinding machines are less versatile than cylindrical grinders and internal grinding machines, but they are simpler in design.

Surface grinding machines are designed to machine the plane surfaces of workpieces with the periphery or the end of a grinding wheel. In machines that use the periphery of the wheel (Figure 1,f), the table and the workpiece mounted on it execute a reciprocating or rotary motion; the rotating grinding wheel is moved crosswise for each traverse or rotation of the table, and it is also shifted by an amount equal to the depth of the cut. In surface grinding machines that machine with the end of the wheel (Figure 1,g), unlike machines that use the wheel periphery, there is no transverse feed, because the diameter of the wheel is greater than the transverse dimension of the workpiece (infeed grinding).

Specialized grinding machines are usually designed to machine parts of some given shape, for example, crankshaft journals, parts of dies, templates, and splined parts. The workpieces are usually machined to a template (the forming method); the generating method is less often used.

The general group of grinding machines also includes lapping, polishing, microfinishing, tool-grinding, spline-grinding, honing, and other machines that use an abrasive tool.

GROUND JOINT, a joint whose surfaces are ground to form a hermetic seal between glass, quartz, or metal parts. [29–1294–2]

HALIMODENDRON, a genus of small (0.5–2 m tall) deciduous thorny shrubs of the family Leguminosae. The leaves are bipinnate and compound; their stalks harden and turn into thorns. The corolla ranges in color from violet to almost white. The pods are usually obovate. *Halimodendron* are found mainly in saline soil. Drought-resistant ornamentals, they are suitable for landscape gardening, particularly in arid steppe and semidesert regions. The sole species, *H. halodendron*, occurs in Iran, Mongolia, and China. In the USSR it grows in the lowlands of the Don, eastern Transcaucasia, Western Siberia, and Middle Asia. [29–604–3]

HATCHED-WARE CULTURE, an archaeological culture of eastern Baltic tribes widespread during the early Iron Age (seventh century B.C. to fifth century A.D.) in central Byelorussia and eastern Lithuania.

Identified by A. N. Liavdanskii in the 1920's, the culture was named for the method of ornamenting modeled vessels with hatching. It arose on the basis of local cultures of the late Bronze Age and is known chiefly from ancient town sites. Early sites were poorly fortified, while later ones were surrounded by one or several earthen banks or ditches. Traces of iron-making were also discovered. Among the objects found were iron spearheads, axes, sickles, spurs, knives, and awls and bronze ornaments. No burials of the hatched-ware culture have been found. By the middle of the first millennium A.D., the population no longer lived in fortified towns but in unfortified settlements. The tribes of the culture engaged in slash-and-burn farming, stock raising, hunting, fishing, and gathering.

HATS, an 18th-century Swedish political party. Formed in the 1730's, it represented the interests of certain elements in the nobility and of some leading members of the bourgeoisie, especially those living in the capital. The party sought to revenge Sweden's defeat in the Northern War of 1700–21 and to restore the country's influence in foreign affairs and its military might through the rapid development of industry and a rapprochement with France.

The Hats came to power in 1738 after gaining a majority in the Riksdag and bringing down the government of A. Horn. Strong opposition to the party, however, arose as a result of Sweden's defeat in the war with Russia of 1741–43, which the Hats had instigated, and the inflation and financial collapse caused by the country's participation in the Seven Years' War of 1756–63. In 1765 the Hats, who had become increasingly identified as the party of the conservative nobility, were displaced from power by the party known as the Young Caps (*see* CAPS). From 1769 to 1771 the Hats again had a majority in the Riksdag. The palace revolution of 1772 led to the abolition of political parties, including the Hats. [29–1307–3]

HAYMARKET SQUARE RIOT OF 1886, a demonstration by workers in Chicago that took place May 1, 1886, under the ban-

ner of the struggle for an eight-hour workday. It involved participants in a strike by workers of industrial and commercial enterprises that had started that same day and that had totally paralyzed the business life of the city. Demonstrations and mass meetings also took place on the following days. On May 4, during a mass meeting at Haymarket Square, an anti-working class provocation occurred: a bomb thrown into a police detachment killed several policemen and workers. This event brought about the arrest of the workers' leaders, four of whom were later sentenced to death and were hanged on Nov. 11, 1887.

The Haymarket Square Riot of 1886 and the subsequent demonstrations and mass meetings of solidarity with its participants marked the awakening of the political consciousness of the US working class. In memory of the uprising, the Paris congress of the Second International in July 1889 passed a resolution to hold yearly demonstrations on May 1. In 1890, May Day was celebrated as an international workers' holiday for the first time.

HÉBERT, JACQUES-RENÉ. Born Nov. 15, 1757, in Alençon; died Mar. 24, 1794, in Paris. Figure in the French Revolution; member of the political club known as the Cordeliers and a leader of the left Jacobins.

Hébert founded the newspaper *Le Père Duchesne* in 1790. It won popularity among the lower classes through its topicality and through Hébert's ability to sense the mood of the masses and to give the mood witty expression in simple language.

Hébert took part in the popular uprising of Aug. 10, 1792, and became deputy procurator of the Paris Commune in December of that year. He waged a bitter struggle against the Girondins. Under the Jacobin dictatorship he advocated the use of extreme methods of terror and took a leading role in carrying out the policy of dechristianization. Hébert fought to purge the National Convention first of the Girondins and the Marais and then of the right-wing Jacobins. He was among those who instigated the arrest of the Enragés, although he supported the Enragés' demand for a ceiling on prices.

In March 1794, Hébert and his supporters—the Hébertists—began agitating against the Jacobin government. After calling for a popular uprising, Hébert and the other Hébertists were arrested, tried by the Revolutionary Tribunal, and guillotined. [29–1629–2]

HÉBERTISTS, during the French Revolution, a left Jacobin faction that took its name from J.-R. Hébert, one of its leaders. The Hébertists, who included A. F. Momoro, F. N. Vincent, and C. Ronsin, were tried as a group in the spring of 1794.

The faction formed during the winter of 1793–94 and, in large measure, reflected the social discontent of the poorer elements of the working people. The Hébertists advocated an intensification of revolutionary terror. They demanded strict observance of the Law of the Maximum and called for relentless struggle against speculation and sabotage by large-scale landowners and well-to-do peasants. They supported the policy of dechristianization and sought to expel G. J. Danton's right-wing Jacobins from the National Convention and the ministries.

Demanding greater severity in the reign of terror against speculators and enemies of the revolution, the Hébertists threatened in March 1794 to lead a revolt against the Committee of Public Safety. They hoped to purge the government of moderates, but they received no support from the Paris Commune or the revolutionary masses. Arrested by the government on March 14, the Hébertists were tried by the Revolutionary Tribunal and, on March 24, guillotined. [29–1630–5]

HELMET, a form of protective headgear. Helmets made of wood, birch bark, plaited twigs, and leather appeared in prehistoric times, and others decorated with feathers and carvings have been described by ethnographers. Ancient helmets made of copper and gold have been found in the royal tombs of Ur and date from the third millennium B.C. When there was a shortage of metal in ancient Egypt, warriors wore small, round, leather or linen caps that were sometimes reinforced with metal plates. Low copper helmets were worn in Babylonia, and a conoidal helmet better than any other existing helmet for deflecting blows was developed in Assyria. The bronze and iron helmets of the Greeks had high crests, and iron helmets were used in ancient Rome. The hemispherical metal helmets commonly used in Western Europe during the early Middle Ages were replaced in the tenth century by conical helmets; one of the ancient Russian helmets found at the Gnezdovo burial mounds is an example of the latter type.

Helmets with a beaver that covered the face appeared in the 13th century in Western Europe. Spherical, visored sallets with a beaver and helmets that covered the entire head were typical of the 14th through 16th centuries. Excavations of such sites as the Gnezdovo burial mounds and the Chernaia Mogila indicate that the basic Russian helmet from the tenth century through the 17th was a pointed, conoidal helmet (*shishak*), camailed to protect the neck and shoulders. The ancient Russian helmets used before the Mongol conquests had nasals as well as masks that covered the entire face.

Some Russian helmets—for example, the helmet of Prince Iaroslav Vsevolodovich, found at the site of the battle of Lipetsk—bore embossed images. Richly decorated helmets of the 13th through 17th centuries were preserved in the Armory of the Kremlin. Hemispherical helmets with a neckguard, earpieces, a visor, and a nasal were widely used by cavalrymen of Eastern and Central Europe during the 1500's. A low, flat helmet (in Russian, *misiurka*) was also used.

After the 17th century, helmets became lighter. Sometimes decorated with crests and plumes, they were called casques. The shape of the *budenovka*, the headgear worn by members of the Red Army, derives from the Russian pointed helmet. Steel helmets—called *kaski* in the Soviet Army until 1939—were introduced in World War I. Since the early 1900's, the special protective headgear worn by pilots, tank crews, and skiers have also been called helmets.

HELMET, COMMUNICATIONS, headgear in the form of a helmet and equipped with an electroacoustical headset consisting of two earphones and either a microphone with a low sensitivity to ambient noise or two laryngophones. Communications helmets are intended for personnel who work under very noisy conditions, for example, in airplanes or tanks.

The helmet, which is made of fabric or leather and is lined with acoustic insulation, covers the entire head except the face. When laryngophones are used, the helmet also covers the neck. The earphones are snugly fitted into acoustically insulating pads sewn into the helmet; the edges of the pads are pressed against the head around the ears. The microphone is in a special holder near a corner of the mouth. The laryngophones, which are usually employed at noise levels exceeding 120 decibels, are fastened to the neck at the larynx. The headset is connected to equipment for intercommunication, outside communication, or both. [29–1287–1]

HERBERT, EDWARD (First Baron Herbert of Cherbury). Born Mar. 3, 1583, in Eyton-on-Severn, Wales; died Aug. 20, 1648, in London. English philosopher, poet, and political figure.

Herbert served as British ambassador to France between 1619 and 1624. During the Civil War he was an adherent of the parliamentary opposition. Herbert was the founder of English deism in the form of natural religion, the source of which he considered to lie not in discovery, but in the innate principle of reason. Herbert summed up the basic principles of natural religion in the following five points: there is a god; he must be worshipped; the best way to worship is through virtue and piety; crimes and transgressions must be atoned for through repentance; there are rewards and punishments in a life beyond the grave. Herbert's moderate deism met with a sharp reaction from theologians. Herbert's doctrine of cognition is based on his acknowledgement of innate ideas. Herbert's views were criticized by J. Locke and P. Gassendi.

HEREDITARY FEUDAL LEASE, in feudal law, the standards formulated in Europe in the 13th and 14th centuries to govern a specific type of land tenancy by peasants and mountaineers. The lease was similar to the emphyteusis in Roman law. It secured for a family the use of a piece of land from generation to generation; the tenant was required to pay the feudal lord a fixed quitrent, usually rendered in cash rather than in kind. This quitrent was known as *czynsz* in Polish, *Zins* in German, *cens* in French, and census in English.

In Western Europe, the use of the hereditary feudal lease spread as the *corvée* system of peasant exploitation declined; the *corvée* system became unprofitable for feudal lords as a result of the development of commodity-money relations. In Central and Eastern Europe, the use of the hereditary feudal lease was sharply restricted in the 16th and 17th centuries by the second promulgation of serfdom. In Russia, the lease, which was known as *chinshevoe pravo*, was used only in limited areas, including the Polish and Lithuanian lands and certain southwestern provinces.

[29–612–4]

HERRINGBONE GEAR, a spur gear with V-shaped helical teeth. The mutual inclination of the tooth segments on opposite sides compensates the axial thrust produced by single helical gears. Herringbone gears afford smooth operation and increased load-carrying capacity, which are characteristic of helical gear transmissions in general. They are used in medium-size and large transmissions, including special transmissions operating at pitch-circle velocities up to 200 m/sec (turbine reduction gears).

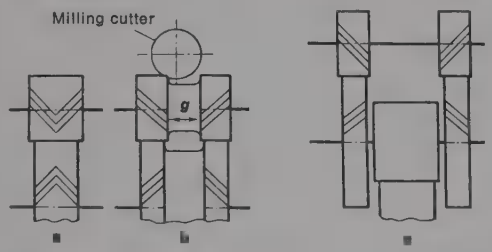

Figure 1. Herringbone gears: (a) continuous-tooth type, (b) double helical gears, (c) two pairs of gears

Continuous-tooth herringbone gears (Figure 1,a) require special equipment to machine the teeth. Double helical, or conventional herringbone, gears (Figure 1,b) have a gap, or groove, where the two sets of teeth meet; they may be made on ordinary gear-hobbing machines, but the width of the gear wheel must be increased by the width of the groove *g*. Transmission through two pairs of helical gears with opposed teeth (Figure 1,c) enables the space between the gears to be used for another transmission.

[29–1070–1]

HEURISTIC. (1) Heuristic methods of solving problems are usually contrasted to formal methods of solution, which are based on exact mathematical models. Heuristic methods, or heuristics, require less time than do methods involving an exhaustive, undirected search of all possible alternatives. Solutions obtained by heuristic methods are generally not optimal; they merely belong to the set of permissible solutions. The employment of heuristic methods does not always lead to the achievement of the goal set. In psychological and cybernetic literature, the term "heuristic" is sometimes applied to any method aimed at reducing the checking of alternatives or to inductive methods of problem solving.

(2) With respect to the organization of the process of productive creative thought, the term "heuristic" is sometimes applied to the mechanisms innate in man by means of which procedures for the solution of problems are engendered. Examples are mechanisms used to establish relations between elements of a problem situation, to eliminate unpromising approaches, and to form refutations with counterexamples. Such mechanisms, which in their aggregate define the metatheory of the solution of problems involving creative thought, are universal in character and independent of the specific problem being solved.

(3) Heuristic programming is a special method of programming for computers. In ordinary programming the programmer expresses a prepared mathematical method of solution in a form comprehensible to the computer. In heuristic programming, however, he attempts to formalize the intuitively understood method of problem solving that he believes a human being would use in solving problems similar to the one at hand. Like heuristic methods, heuristic programs do not necessarily ensure that the goal set will be attained or that the result will be optimal.

(4) The branch of the science of thought that studies heuristic mechanisms or procedures is known as heuristic. Its main subject is creative activity (*see* CREATIVITY), and its principal problems involve models for decision-making in nonstandard problem situations, for seeking that which is new to a person or society, and for structuring descriptions of the external world through classifications like the periodic table of the elements or C. Linnaeus' system for plants and animals. The science of heuristic draws on psychology, the theory of artificial intelligence, structural linguistics, and information theory.

(5) The term "heuristic" is sometimes applied, particularly in the Soviet literature, to a special method of teaching (Socratic method) or of group solution of problems. Heuristic teaching, in this sense, consists in asking the students leading questions and providing the students with suggestive examples. This method of instruction dates back to Socrates. In the group method of solving difficult problems known as brainstorming, creative thought is stimulated through freewheeling discussion. When a group member suggests an idea for a solution, the other members supply leading questions, examples, and counterexamples.

HEXABIBLOS OF HARMENOPULUS, a private codification of Byzantine law, compiled by the supreme judge of Thessalonica, C. Harmenopulus, circa 1345. The *Hexabiblos* was the last important monument of Byzantine law; it drew on previous codifications, such as the Digest and the nomocanons. The *Hexabiblos* of Harmenopulus was widely used in Greece during the period of Turkish supremacy (since the Greeks retained special jurisdiction) and after the liberation of the country. The codification was also widely used in Bessarabia. It was divided into six books, each of which dealt with a given topic—legal procedure, real law, liability, inheritance, laws relating to marriage, and criminal law.

[29–1157–2]

HEXACTINELLIDA (or Hyalospongia), a class of sponges. Hexactinellida are predominantly solitary, typically oceanic organisms, usually occurring at depths of more than 100 m, down to the hadal (or ultra-abyssal) zone. The body is saclike, tubular, goblet-shaped, or barrel-shaped, up to 2 meters in height. The

skeleton consists of six-rayed siliceous spicules. The rays lie in three mutually perpendicular planes; in some of the needles, one or more rays are reduced. The canals that thread through the body wall (the canal system) are of the simple leuconoid type.

The class comprises about 500 species, 34 of which are found in the USSR—six in northern seas and 28 in Far Eastern seas. The most common are representatives of the genera *Hyalonema, Aphrocallistes, Schaudinnia, Aulosaccus, Acanthascus*, and *Caulophacus*.

The skeletons of some Hexactinellida are used for decorative purposes.

HINGE LINE, a line connecting the points of maximum bending of the strata in a fold. If a series of strata is compressed into a

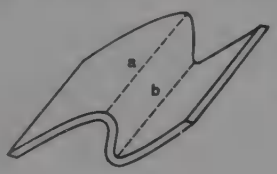

Figure 1. Hinge lines: (a) the hinge line of an anticline, (b) the hinge line of a syncline

fold, each stratum has its own hinge line, and the plane that passes through the corresponding series of hinge lines is called the axial surface of the fold. [29–862–4]

HOBBY (*Falco subbuteo*), a predatory bird of the family Falconidae. The body length is 33 to 35 cm. The upper parts are black with a blue sheen, and the underparts, light with dark markings. The hobby is distributed in Europe, Asia, and North Africa; in the USSR it is found in the forest and forest-steppe zones and in the mountains of the Caucasus and Middle Asia. A migratory bird, it winters in southern Africa and Asia. In the spring it arrives no earlier than late April. It nests in trees in the abandoned nests of crows and other birds. The clutch contains two to four, sometimes five or six, eggs, which are incubated for 28 days. The hobby catches its prey in flight, attaining speeds of up to 150 km/hr. The diet includes small birds and insects, such as dragonflies and beetles. The hobby was formerly used as a hunting bird.

HODGSON'S HAWK CUCKOO (*Hierococcyx fugax*), a bird of the suborder Cuculiformes. The Hodgson's hawk cuckoo measures about 30 cm in length. It is distributed in Southeast Asia and in the USSR, where it is found in the forests of southern Primor'e. (*See* CUCKOO.) [29–1228–7]

HOHENSTAUFEN (also Staufen), a dynasty of German kings and Holy Roman emperors (1138–1254); a Swabian princely family that ruled the duchy of Swabia (1079–1268).

The Hohenstaufens took their name from their ancestral castle of Staufen in Swabia. The Hohenstaufen kings and emperors were Conrad III (1138–52), Frederick I Barbarossa (1152–90), Henry VI (1190–97), Philip of Swabia (1198–1208), Frederick II (1212–50), and Conrad IV (1250–54). The dynasty's prolonged struggle against the Welfs (Guelphs) began during the reign of Conrad III. Under Henry the dynasty took control of the Kingdom of Sicily.

The last Hohenstaufens were Manfred, who reigned as king of Sicily (1258–66), and Conrad IV's son Conradin (died 1268); both perished in battles against Charles I of Anjou, who had come to southern Italy at the request of the Hohenstaufens' enemy the pope. [29–1461–1]

HONOR AND DIGNITY, LEGAL PROTECTION OF, a personal, nonproperty, inalienable right safeguarding the recognition by a person of his social significance and the recognition by society of the individual's significance.

The right of the citizens of the USSR to protection by the courts against encroachments on their honor and dignity is guaranteed by Article 57 of the 1977 Constitution of the USSR. Honor and dignity are also protected by civil and criminal legislation (*see* DEFAMATION and INSULT). Citizens or organizations have the right to demand in court the retraction of statements damaging to their honor or dignity unless the person who has spread the statements shows that they are truthful. Article 7 of the Basic Principles of Civil Legislation of 1961 and the corresponding articles of the civil codes of the Union republics protect the honor and dignity of a person in cases where defamatory statements are spread innocently—that is, where the person responsible for the statements believes them to be true. The essential distinction between protection of honor and dignity under criminal and under civil legislation rests on the difference between slander and the innocent spreading of defamatory statements.

Defamatory statements may be spread in oral or written form: they may be spoken to one or more individuals or to a group of people, or they may be printed in published or other written works. If the statements appear in the press and are not truthful, they must be retracted in the press. In other cases, the procedure for retracting the statements is established by the court; for example, oral statements may be retracted at a trade union meeting, and written ones, in a wall newspaper. If the retraction is not made in accordance with the judicial decision, the court has the right to impose a fine on the violator; payment of the fine does not release the violator from the obligation to fulfill the decision of the court (Code of Civil Procedure of the RSFSR, art. 406). The money from the fine is added to the state's income. Soviet legislation does not provide for any compensation of a monetary character for personal injury (*see* PERSONAL INJURY).

Cases dealing with the protection of honor and dignity may be heard by people's courts and comrades' courts. The statute of limitations for claims does not apply to demands for the retraction of defamatory statements. [29–345–1]

HOROLOGIUM (the Clock), a constellation of the southern hemisphere; its brightest star has a visual stellar magnitude of 3.9. The constellation is most easily viewed in November; it is partly visible from the southern regions of the USSR. (*See* STELLAR SKY.) [29–103–1]

HOSIERY, a category of knitwear including knitted socks, full-length stockings, panty hose, footgloves, and other articles. The range of hosiery may be classified by consumer type (women's, men's, children's, athletic), material (plain polyamide, elastic, cotton, wool, mixed), and knit structure (plain, stretch, reversible, knitted plush, ravel-resistant), as well as by the manner of manufacture, the trim, and other factors.

Hosiery is usually made on hosiery machines. In order to increase the durability of items made of cotton or wool yarns, the heel and toe are reinforced with another yarn, usually of polyamide. The upper edge of socks and half-length stockings is usually knitted with an additional elastic or spandex-type yarn, which makes the cuff resilient and able to stretch. A tucked knit is used in knitting articles made from plain polyamide yarn in order to reduce raveling. Panty hose are usually made by sewing together two long stockings; a gusset is sewn in to increase the dimensions in the torso, and an elastic waistband is attached. Panty hose made from elastic yarn may also be manufactured without sewing.

Hosiery sizes are measured by the length of the foot in centimeters; there are two subsizes for the length of the sock or stocking. I. I. SHALOV [29–758–1]

HOSIERY MACHINE, a knitting machine for manufacturing hosiery. Circular knitting machines are the most common type, producing approximately 95 percent of all hosiery made. They are characterized by continuous loop formation and the absence of high alternating loads.

Circular knitting machines are used to knit all types of hosiery. The raw materials used are chiefly polyamide and cotton yarns. Machines of this type have internal specialization for various types of finished products. Women's socks are usually made on single-cylinder (single-knit) machines with two, four, or eight loop-forming systems. The primary working elements are latch needles, housed in grooves along the periphery of a needle cylinder, and sinkers set in radial grooves of a ring around the upper edge of the cylinder. The motion of the needles and sinkers along the grooves of the rotating cylinder is imparted by fixed cams that act on the base of the needles and the sinkers. The interaction of the needles and sinkers with the yarn, which is fed to the needles from bobbins through a yarn guide, forms the loops. The sock is drawn through the inside of the needle cylinder by a current of air from a special fan. The finished sock is then tossed into a bin. The toes are usually sewn on special sewing machines (linking or serging types). The newest automatic circular hosiery machines complete the sock with a closed toe.

Patterned full-length stockings are knit on single-cylinder hosiery machines equipped with a pattern mechanism. Three- and four-system machines can knit stockings in three and four colors, respectively. Two-cylinder (double-knit) automatic circular machines are used chiefly to make children's socks and all types of full-length stockings. Their main distinction is that they knit articles with high extensibility (ribbed fabrics). The primary working element of such machines is a two-headed latch needle that can be automatically shifted from the lower needle cylinder to the upper and back again. This type of needle motion is used to switch to ribbed (double-face) or reversible knit structures.

Technical specifications for hosiery machines include the diameter of the needle cylinder (2.5–4.5 inches), the number of needles in the cylinder (40–480), the gauge (measured by the number of needles to 1 inch of the cylinder circumference), the number of loop-forming systems (from one to 12), and the presence of special mechanisms. The productivity of hosiery machines varies greatly, depending on the type of article and the type of machine. The time it takes to knit a woman's sock varies from 1 to 4 min; full-length stockings require from 0.5 to 4 min.

Small quantities of hosiery are manufactured on flat knitting machines and sometimes on ribbers and circular warp-knitting machines.

HULLING MILL, a machine for hulling (removing the shell from the kernel) rice and oats for the production of groats. The principal working member consists of two horizontal millstones; the lower turns on a vertical axis, and the upper is fixed. The working surfaces of the millstones are coated with an abrasive. Grains are loaded into the gap between the millstones, where they are compressed and subjected to friction, which frees the kernels from the shells. The intensity of hulling depends mainly on the clearance between the millstones, which is regulated by a special lifting device. Hulling mills with millstones 1.25 m in diameter can process from 0.33 to 0.5 kg of grain per sec, depending on the type of grain. (*See* GROATS PRODUCTION.) [29–1118–2]

HUMAN FACTORS, in technology, the characteristics of a human being or a group of people and of a machine or a technical system that are manifested under specific conditions of interaction in a man-machine system, whose operation is governed by the performance of a specific task. Human factors are related primarily to the aspect of the man-machine interaction that is specified by human activity. The correct combination of human abilities and machine capabilities substantially improves the effectiveness of a man-machine system and leads to the optimum utilization by man of technical means for their intended purpose.

The consideration of human factors is an integral part of the design, development, and use of machines and technical systems and is a necessary condition for raising the productivity of labor and the quality of production. Such consideration is most complete in the designing of the human activity in man-machine systems. The designing of a specific type of activity entails the study of man's internal means of activity—for example, his experience, knowledge, skills, perceptions, thoughts, and memory—and the coordination of the internal means with such external means as documents, algorithms, tools, and manual controls in accordance with the basic operational task of the system that is devised. The design that is developed is used to formulate the requirements for the system's machine component, which man uses to carry out the specific type of activity.

A distinction is made between the concepts of human factors and the personal factor. In contrast to human factors, the personal factor, which was introduced in connection with the study of human errors involved in industrial and transportation accidents, includes the individual characteristics of a man irrespective of the characteristics of the technical means with which the man interacts. The concept of human factors is relatively new; it arose in connection with the study and design of man-machine systems as a functional whole (*see* SYSTEMS ENGINEERING and SYSTEMS APPROACH).

One of the first attempts in the USSR to shed light on the concept of human factors was undertaken in 1930 by the Soviet scientist N. M. Dobrotvorskii. However, the term "human factors" was later introduced into Russian as a result of the translation and shortening of the expression "human-factors engineering," which is used in the USA to denote both a branch of knowledge and the process of designing man-machine systems with the goal of ensuring effective, reliable, and safe human activity, whether by one person or by a group of people.

In the USA, the Human Factors Society was founded in 1957, and the journal *Human Factors* was first published in 1958. In European countries, including the USSR, the term "ergonomics" is used to denote the specific field of knowledge and the area of professional activity that are analogous to what is called human factors in the USA. (*See* ENGINEERING PSYCHOLOGY and MAN-MACHINE SYSTEM.)

HUMAN RELATIONS THEORY, a concept regarding the principles and goals of management in organizations, especially in industry, that developed in bourgeois social science. The theory arose in the 1920's in the USA as the attitudinal and methodological basis of the industrial sociology of labor. Its leading advocates were F. J. Roethlisberger, W. E. Moore, and E. Mayo in the USA and G. Friedmann in France.

Human relations theory developed as a response to Taylorism. Rejecting the biological and mechanistic approaches of F. W. Taylor's "scientific management," the human relations theory proposed the implementation of methods of dealing with workers as sociopsychological beings. As the basis of its new methods of intensifying and increasing labor productivity, the human relations theory proposed that human psychological and moral qualities—such as goals, motivation, and values—be taken into account. The use of empirical data on worker satisfaction with labor and the influence of collective demands and of the psychological climate in work groups on labor productivity spurred attempts to develop a program to harmonize the relations of different groups and individuals in order to bring about maximum efficiency in the operation of the organization as a whole. The program took into account requirements arising from modern technological progress. New technology and the automation and mechanization of production processes placed in the forefront the task of training workers capable of continual improvement of work habits. Moreover, it was determined that sweatshop methods of increasing worker productivity were ineffective. The practical needs of capitalist production encouraged the study of important problems within the framework of the human rela-

tions theory; such problems included factors fostering a positive or negative attitude toward labor and the influence of the work group on the individual; the effectiveness of forms and methods of supervision; and the improvement of conditions for work, relaxation, and leisure.

The term "human relations theory" reflects an attempt by bourgeois ideologists to pass off a program of measures as the humanization of labor that are of practical value for increasing profits. In fact, the human relations theory attempts to conceal or rationalize the profound social conflicts of capitalist society.

N. V. NOVIKOV [29–151–1]

HYMENOMYCETES (also Macromycetes), a group of higher fungi that usually have large fleshy fruiting bodies most often consisting of a cap and stalk. Most belong to the class Basidiomycetes (for example, *Boletus edulis, Snillus luteus, Lactarius piperatus, Russula vesca, Armillariella mellea*, and *Amanita muscaria*). Some belong to the class Ascomycetes (for example, *Morchella esculenta, Gyromitra esculenta*, and *Tuber melanosporum*). Sometimes only basidiomycetous mushrooms of the order Agaricales are referred to as Hymenomycetes. [29–1308–1]

ICE CHUTE, FRAZIL, a device that makes possible the passage of frazil ice through or around a hydroengineering complex, from the upper pond to the lower pond or from the canal. An ice chute usually consists of an ice receptacle installed cross-current, often in the shape of a trough, which intercepts the top layer of water containing the floating frazil ice, and an outlet, which directs the frazil ice to the lower pool or out of the canal. Frazil ice may also be removed through the spillways of a dam or the drop valves in the gates. Also used are ice-chute designs based on the use of specially created eddy craters in the hydroengineering complex' upper pool that carry the frazil ice down to outlets at the bottom. [29–1521–4]

IDEHAN MARZUQ (also Murzuq Sand Sea), a sandy desert in southwestern Libya. Idehan Marzuq is situated in a depression bordered by outlying massifs 450–500 m in elevation. It occupies an area of approximately 200,000 sq km. In the north and northwest there are dunes up to 300 m in height, which are devoid of vegetation. Annual precipitation is approximately 10 mm. Oases with date palms are found along the northern and eastern borders. [29–1679–5]

IDEHAN UBARI (also Ubari Sand Sea), a sandy desert in Libya, located at an elevation of 400–500 m. The relief mainly features ridges, although isolated dunes with a relative height of up to 200 m are found. Annual precipitation is approximately 10 mm. The desert is almost devoid of vegetation. The depressions have salt marshes and lakes, from which soda and salt are mined. There is nomadic animal breeding. Around the borders of the deserts there are small oases with groves of date palms. [29–1679–6]

IJMUIDEN, a city and port in The Netherlands, in the province of North Holland; situated on the North Sea. IJmuiden is the outer port of Amsterdam, with which it is connected by the North Sea (Amsterdam) Canal. It is part of the Amsterdam conurbation. IJmuiden is a center for ferrous metallurgy and has enterprises of the chemical and cement industries. [29–1719–1]

IJSSEL, a river in The Netherlands. The IJssel, a right branch of the Rhine, originates near the city of Arnhem. It measures 123 km in length. The river empties into the IJsselmeer, the southern part of the Zuider Zee, after flowing through a plain in an embanked channel. The mean flow rate is approximately 280 cu m per sec, and the maximum flow rate is approximately 2,000 cu m per sec. In the winter the water level rises 4–7 m. The IJssel is navigable for its entire length. A network of canals connects it with the northern and eastern parts of the country. The cities of Deventer and Zwolle are located in the valley of the IJssel. [29–1729–5]

ILTUTMISH, SHAMS AL-DIN. Ruler of the Sultanate of Delhi (1211–36). Member of the Ghulam (Slave) dynasty.

Of Turkic origin, Iltutmish was a *ghulam* (slave) of Qutb al-Din Aibak, who founded the Sultanate of Delhi; he later became a *mukta* (governor) of several districts. He annexed the Punjab and Sind to the sultanate and successfully warred against the Indian princes. In 1229 he was recognized as an independent ruler (sultan) by the Baghdad Caliphate. Under Iltutmish, large religious structures were built in Delhi. [29–829–2]

IMBRICATE STRUCTURE, a tectonic structure characterized by relatively thin and elongated rock sheets that overlap one another. The thickness of the rock sheets ranges from a few meters to a few hundred meters. Imbricate structures are usually found in series, forming groups of closely spaced folds, low-angle thrust faults, or fault-folds. In folded regions, they form imbricated fault zones. The amplitude of displacement may reach several kilometers but is usually not greater than a few hundred meters. [29–531–1]

INK SAC, an organ in most cephalopods, for example, octopuses, cuttlefish, and squids, in which a fluid is formed containing granules of a black pigment of the melanin group.

The ink sac, which serves a protective function, consists of a glandular portion and a reservoir, which opens into the rectum through a duct. Old cells of the glandular portion are gradually destroyed, dissolve in the secretions of the gland, and accumulate in the reservoir. When threatened, the mollusk ejects the contents of the reservoir, creating a dark cloud in the water that serves as a smokescreen to hide the mollusk. The coloring capacity of the inky liquid is unusually high; for example, the cuttlefish can color the water of a tank holding up to 5,500 liters in 5 seconds. A dye, natural sepia, has been obtained from the dried contents of the ink sac treated with potassium hydroxide. [29–250–4]

INTERLACED SCANNING, a method of television scanning in which the transmitted image on the target of the television camera tube and the television frame on the screen of the picture tube are produced by a single scanning of two frame fields; the odd lines are scanned and reproduced for the first field, and the even lines, which are positioned in the spaces between the lines of the first field, make up the second field. When scanning of the second field has been completed, the beam is returned to the point where the scanning of the first field begins.

Interlaced scanning is used in television systems with an odd number of scanning lines z because only in this case is there a nonintegral number of lines $z/2$ in each field, so that the beginning of scannings of the first and second fields (and, as a result, the television rasters of these fields) are displaced along the vertical by half the displacement of adjacent lines in a field. It permits a 2:1 reduction in the frame frequency needed for line scanning (since the flicker frequency of the images on the screen is equal to the field frequency) and thereby reduces by half the upper frequency limit of the television signal spectrum.

N. G. DERIUGIN [29–219–1]

INVOLUTE GEARING, a gear tooth system in which the tooth contours are described by the involute of a circle, known as the base circle.

Figure 1 shows the involute tooth system of a gear train. The tooth contour of gear wheel 1 is described by the involute I_1 of the base circle with the radius r_1, and the tooth contour of gear wheel 2 is described by the involute I_2 of the base circle with the radius r_2. The involutes I_1 and I_2 are tangent at the point C. Ac-

cording to the conditions for the construction of an involute, the normal to involute I_1 at the point C must be tangent to the base circle with the radius r_1 and the normal to involute I_2 must be tangent to the base circle with the radius r_2. From this it follows that in an involute tooth system the common normal to the contiguous contours of the teeth always coincides with the common tangent

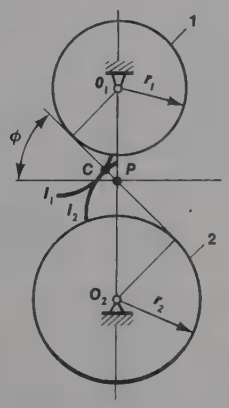

Figure 1. Involute gearing: (1) and (2) gear wheels

to the base circles. This tangent is known as the line of action because the point of contact between the teeth moves along the line as the gear wheels move. The point P where the line of action intersects the line of centers O_1O_2 is called the pitch point, and the angle made by the line of action with the perpendicular to the line of centers is the pressure angle ϕ. The gear ratio m_G, that is, the ratio of the angular velocities of gear wheels 1 and 2, is given for involute gearing by $m_G = O_2P/O_1P = r_2/r_1$. It is therefore evident that with involute gearing a change in the center distance does not affect the gear ratio but only the pressure angle. Involute gears are the most common type in use.

N. I. LEVITSKII [29–1653–2]

INVOLUTE-PROFILE-MEASURING INSTRUMENT, an instrument designed to measure the contours of involute gear teeth in a section perpendicular to the axis of the gear wheel. It functions by comparing an involute generated by the instrument with the actual involute of the tooth profile. Depending on the design of the mechanism for generating the involute, such gauges are classified as individual (disk) and universal types. In a disk-type instrument, the comparison curves are reproduced by means of interchangeable disks having diameters equal to those of the base circles of the gear wheels being checked. In universal instruments the curves are reproduced by a special device that is adjusted for the different radii of the base circles. Among the most popular of the latter type are instruments in which the generating mechanism contains a disk of fixed diameter and a lever-band linkage or a mechanism having a fixed involute template and a lever linkage. The disk-type instruments are the most accurate.

Involute-profile-measuring instruments are made in several standard sizes for measuring tooth contours of both internal and external gear wheels having base circle diameters usually between 40 and 1,250 mm. They are usually provided with an auxiliary device for measuring the helix of helical gear wheels (*see* WORM GAGE) that moves the measuring point of the indicating mechanism along the axis of the gear wheel being measured as the wheel turns. Measurements are usually obtained by means of a recorder.

A promising advance in the development of involute-profile-measuring instruments is a system that uses pulses from a transducer and a miniature computer. In a number of such instruments the gear wheel being measured is rotated and the measuring point is shifted so that pulses that are proportional to the angle of rotation of the gear wheel and to the linear movement of the point arrive simultaneously at the computer. The data are compared in the computer with theoretical values previously supplied. In other versions the theoretical angles and the linear movements of the gear wheel and measuring point are provided by the computer, and the indicating device gives the deviation of the actual contour from the theoretical values.

N. N. MARKOV [29–1653–3]

IRON AND STEEL MONOPOLIES. Ferrous metallurgy in the capitalist countries is characterized by a high degree of concentration and monopolization of production. The five largest monopolies account for approximately one-fourth of the capitalist world's steel production.

Until the 1960's, the level of concentration and monopolization of production in the US iron and steel industry was significantly higher than in Western Europe and Japan, where a rapid procession of mergers and take-overs in the industry took place in the 1960's. In the Federal Republic of Germany (FRG), the steel firms August Thyssen-Hütte AG, Krupp, and Hoesch-Werke AG increased their economic power by absorbing several companies. Thus, in 1973, August Thyssen-Hütte AG, after having absorbed the firm of Rheinstahl AG, controlled more than 30 percent of the steel production capacity of the FRG. Japanese iron and steel companies, which had rapidly introduced and improved advanced foreign technology and which used modern methods for the intensification of labor, occupied a leading position in world steel production by the early 1970's. In 1970, the firm Nippon Steel became the largest capitalist steel producer through the merger of the two leading Japanese monopolies, Yawata Iron and Steel and Fuji Iron and Steel. Upon the nationalization of the iron and steel industry in Great Britain in 1967, 14 private companies were combined into one state firm, British Steel Corporation, which almost completely monopolized the country's smelting of pig iron and steel. In France, the firm of Usinor absorbed Lorraine Escaut in 1966 and became the industry's leading firm in that country, accounting for one-third of French steel production. In 1975 the ten largest iron and steel monopolies included four Japanese, two American, one British, one West German, one Italian, and one Dutch–West German firm (see Table 1).

The iron and steel monopolies of the USA and the countries of Western Europe embrace a network of integrated facilities. They mine or participate in the mining of iron ore, coal, and limestone. Most Japanese companies use imported ore, scrap, and coal. The monopolies produce pig iron, steel, ferroalloys, high-quality steels, rolled products, pipe, steel structures, and semifinished

Table 1. The largest iron and steel monopolies in the capitalist countries
(1975)

	Year founded	Steel production (million tons)	Employees (thousands)	Assets (billion dollars)	Sales volume (billion dollars)	Net profit (billion dollars)
Nippon Steel (Japan)	1970	32.5	98	9.5	8.8	0.1
United States Steel (USA)	1901	24.0	173	8.1	8.2	0.6
British Steel (Great Britain)	1967	17.2	223	6.3	5.3	0.2
Bethlehem Steel (USA)	1904	15.9	113	4.6	5.0	0.2
Nippon Kokan (Japan)	1912	14.7	43	5.8	4.2	0.04
Sumitomo Metal Industries (Japan)	1897	13.4	44	5.6	4.2	0.05
Kawasaki Steel (Japan)	1906	13.4	44	5.5	3.8	0.03
August Thyssen-Hütte (FRG)	1871	12.2	141	4.9	8.8	0.1
Finsider (Italy)	1937	11.4	52	5.7	2.7	−0.1
ESTEL (Netherlands–FRG)	1972	9.6	75	3.8	3.3	−0.08

and finished steel products, as well as refractory materials, rollers, and oxygen. They control large machine-building and shipbuilding enterprises and have large transport fleets and an extensive network of marketing branches covering most capitalist countries.

Until World War II, iron and steel monopolies formed the basis of the military-industrial strength of the imperialist countries. From the 1950's to the 1970's, their importance in the production of military hardware diminished somewhat, and they lost their position to aerospace and electronics monopolies. However, the production of military products (special steels and alloys, armored vehicle and tank bodies, gun barrels, and warships) continues to play an important role in their production programs. The major form of foreign economic expansion of iron and steel monopolies is the export of products, which accounts for approximately 30 percent of the total sales volume of most large firms. Iron and steel production is concentrated at domestic plants; mining facilities supplying ore and minerals are mainly located abroad. However, in the 1960's iron- and steel-producing companies increased their capital export to foreign processing and other metallurgical enterprises. The trend was accelerated in the 1970's as a result of increased production costs and the high cost of environmental protection measures, especially in Western European countries. For example, steel monopolies in the FRG are rushing construction of industrial complexes in Brazil.

The iron and steel monopolies are linked by many cartel agreements; examples are the European Coal and Steel Community (ECSC) and the International Iron and Steel Institute (IISI) in Brussels. Iron and steel monopolies are components of the major financial monopoly groups. At the same time, there are strong state monopolistic trends in the industry: the major iron and steel producers in Great Britain, Italy, and Austria are controlled by the state.

The largest iron and steel monopoly, Nippon Steel, accounts for approximately 8 percent of steel production in the capitalist countries and more than 30 percent of Japanese production. It operates 11 plants and imports ore from Australia, India, and Africa and coal from the USA, Australia, and Canada.

The largest iron and steel company in the USA, United States Steel Corporation, produces approximately 25 percent of the steel and 40 percent of the pig iron in the USA. It exploits iron ore deposits in the USA, Canada, Venezuela, and Brazil; coal deposits in the USA; and deposits of manganese, chromium, and other ores in Brazil, Gabon, France, and the Republic of South Africa. It is controlled by the Morgans and the Boston and Chicago financial groups.

The monopoly Bethlehem Steel Corporation produces 15 percent of the steel in the USA and exploits deposits of iron and manganese ore in the USA, Canada, and the countries of Latin America. It is controlled by the Morgans.

British Steel Corporation was established as a result of the nationalization of steel-producing companies and accounts for more than 85 percent of the steel production and 55 percent of the output of rolled steel in Great Britain.

The second-ranking Japanese iron and steel monopoly, Nippon Kokan, produces about 15 percent of the steel in Japan and also manufactures refractory materials and oxygen. Steel and steel products account for approximately two-thirds of the firm's sales. Nippon Kokan imports iron ore, steel scrap, and coal and is a component of the Fuji financial group.

The Japanese firms Sumitomo Metal Industries and Kawasaki Steel each account for 13 percent of Japanese steel production. Sumitomo Metal Industries is Japan's largest producer of steel pipe, accounting for approximately one-fourth of the country's total pipe production; it is the major industrial company of the Sumitomo financial group. Kawasaki Steel specializes in the production of rolled sheet steel (more than 60 percent of its sales) and is linked to the Sanwa group.

The leading iron and steel company in the FRG, August Thyssen-Hütte, was second in sales among the West German industrial monopolies in 1974 and accounts for more than 30 percent of the steel production in that country. It participates in coal mining in the FRG and in mining iron ore in Brazil, Liberia, and Mauritania. It is owned by the Thyssen family and is a component of the Thyssen-Oppenheim financial group.

The Italian government owns 55 percent of the capital of the firm Finsider, and the remaining portion belongs to major Italian monopoly groups. Finsider controls about 90 percent of the production of pig iron and approximately 50 percent of the steel production in Italy. Its largest steel-producing affiliate is Italsider. It also accounts for almost 40 percent of steel pipe production and owns enterprises engaged in the mining of coal and iron ore.

The Dutch–West German monopoly ESTEL has seven plants in the FRG and four in the Netherlands. Hoesch-Werke AG and Hoogovens Ymuiden BV are branches of ESTEL. Hoesch-Werke AG is the second largest steel producer in the FRG, accounting for 5.2 million tons, or 13 percent of the total production, of steel in 1975. Hoogovens Ymuiden BV is the leading Dutch steel producer. (*See also* FERROUS METALLURGY.)

I. A. AGAIANTS [29–288–1]

JACKAL (*Canis aureus*), also Indian jackal, Oriental jackal, or common jackal, a predatory mammal of the family Canidae. The jackal resembles a wolf but is much smaller and has a shorter tail and more pointed muzzle. The body measures 71–82 cm in length, and the tail, about 20 cm. The fur is reddish brown to gray in the winter and reddish brown in the summer.

The jackal is distributed in southern Europe, North Africa, and southern Asia and on the island of Sri Lanka. In the USSR it is found in the Caucasus and Middle Asia; sometimes it occurs in Moldavia. The jackal usually inhabits lowlands and dense thickets along rivers and lakes; more rarely it inhabits deserts and foothills. It is often found near populated areas. It lives in dens. The diet includes rodents, birds, carrion, garbage, and fruits. Mating occurs in January. The female gives birth to four to nine pups, usually in the den. Sexual maturity is attained in the second year of life. Primarily a nocturnal animal, the jackal has a particularly loud howl.

The jackal has little commercial importance; the hide is of little value. The jackal is somewhat harmful to the hunting trade and poultry farming. [29–811–7]

JAPANESE ANGELICA TREE (*Aralia mandshurica*), a tree of the family Araliaceae. The erect unbranched or slightly branched spiny trunk reaches 12 m in height and 15–20 cm in diameter. The alternate leaves reach 1 m in length and are usually concentrated near the top of the trunk; they are twice or thrice pinnate, with sparse spines on the petioles and main veins. The small white flowers are five-parted and bisexual or staminate; they are gathered in numerous umbels, which in turn form compound inflorescences, measuring as much as 50 cm in length, on the top of the trunk and branches. The fruits are baccate and small.

The Japanese angelica tree grows in the Primor'e and in the southern Amur region. Outside the USSR it is found in Northeast China and Korea. The tree occurs in deciduous and mixed forests, on forest margins, and in burned-out and felled forests. In some places it forms impenetrable thorny thickets. A rapidly growing tree, the Japanese angelica tree is used as an ornamental for solitary and group plantings and for hedges. It has medicinal properties: an infusion of the roots is used as a stimulant. The closely related species *A. elata* grows on southern Sakhalin and in the southern Kurils.

JAW. (1) In animals, any of various organs of different origin used to capture and break up food. Jaws vary in structure among different taxonomic groups and are formed in the course of individual development from different rudiments; that is, they are analogous organs. Jaws exist in several invertebrates, including some worms, mollusks, and arthropods.

In arthropods, modified appendages (extremities) of the head function as jaws. In organisms whose head is fused with the thorax into a cephalothorax, the extremities of the thoracic segments usually serve to capture food, and they are called maxillipeds (crustaceans, chilopods). Particularly characteristic of arthropods is the presence of a pair of upper jaws (mandibles) and two

pairs (less commonly one pair) of lower jaws (maxillae). In insects, a second pair of lower jaws fuse together to form the lower lip. Chelicerata have two pairs of head appendages that perform in part the function of jaws. The chelicerae are used to capture food, while the pedipalpi, located behind them, crush it. Among the echinoderms, sea urchins possess a complex maxillary apparatus called Aristotle's lantern.

All vertebrates are divided into two large groups: those without jaws—the Agnatha, represented by the class Cyclostomata—and those with developed jaws—the Gnathostomata, which constitute all the other classes.

In gnathostomatous vertebrates, the jaws are situated on the facial (visceral) part of the skull. In the course of evolution, they developed first in fish as a result of the transformation of one of the anterior (third) pairs of gill arches. The upper and lower elements became reduced, while the middle portions enlarged to form the primary upper jaw, or palatoquadrate cartilage, and the primary lower jaw, or Meckel's cartilage. Cartilaginous fishes (Chondrichthyes) have only primary cartilaginous jaws, equipped with teeth derived from the placoid scales. In bony fishes, amphibians, reptiles, birds, and mammals, substituting ossifications covered with tectorial bones developed in the posterior portions of the upper and lower jaws, from which secondary jaws then developed. Beginning with the bony fishes, a secondary jaw consisting of the premaxillary and maxillary bones forms the upper jaw. With the development of the secondary jaw, whose bones are situated along the margin of the mouth, the primary upper jaw is pushed back still farther into the palatine region of the skull and in reptiles, birds, and mammals loses its teeth. In some forms, the jaws have no teeth, and they acquire a horny structure (bill).

The development of jaws was a very important stage in the evolution of vertebrates, since it enabled vertebrates to shift from passive feeding to the active seizure of prey.

(2) In humans, the jaws are the largest bones of the visceral cranium. The upper jaw (maxilla) is a paired bone and consists of two superior maxillary bones. It occupies half of the upper part of the face, and its size and configuration greatly influence the shape of the face. Each superior maxillary bone consists of the body, with external surfaces (directed toward the nasal cavity) and posterior surfaces, and four processes—nasal, alveolar, zygomatic, and palate processes. The upper part of the bone, which is in the shape of a bent plate, forms the floor of the orbit. The interior of the body forms a cavity—the maxillary sinus, or antrum of Highmore—which communicates with nasal fossae through an aperture on the internal, or nasal, surface. The alveolar process, the lower margin of the upper jaw, contains eight cavities for teeth. Together with the process of the other supermaxillary bone, it forms the dental alveolar arch.

The lower jaw (mandible) consists of the unpaired inferior maxillary bone of the facial skeleton. This only mobile cranial bone develops from symmetrical left and right halves that fuse in the center and occupies the lower part of the face. It is characterized by a V shape. Two rami project upward vertically or diagonally from the body, or horizontal portion, of the lower jaw. The superior border of the body consists of the alveolar arch, hollowed into 16 cavities for teeth. The end of each ramus breaks up into two processes: the coronoid process, to which the temporal muscle is attached, and the condyloid process, which articulates with the temporal bone. The angle between the ramus and the body varies from 90° to 140°. Nerves and blood vessels pass through the upper and lower jaws to innervate and supply the teeth with blood.

JURCHEN, the language of the Jurchens. Jurchen, which belongs to the Manchurian branch of the Manchu-Tungus languages, is attested in texts written in the Jurchen "large script" and "small script." The large script was created in 1119, evidently by adapting the Khitan writing system to the Jurchen language; it remains undeciphered. The small script was created in 1138 from graphic elements in the Chinese writing system; it contains syllabic signs and ideograms. Some of the texts in the small script are bilingual, with a translation and transcription in Chinese, which made it possible to decipher the small script and obtain an idea of Jurchen. Jurchen is similar to Manchu, which derives from it, in lexicon, morphemes, and structure. (*See* MANCHU-TUNGUS LANGUAGES.)

[29–539–4]

JURCHENS (also Juchen, Jürched), tribes of Tungus origin that from ancient times inhabited the eastern part of Northeast China (Manchuria) and the Primor'e.

Until the tenth century, the Jurchens were independent and maintained ties with China and Korea. In the tenth and 11th centuries they were dependent on the Khitans. In the early 12th century the various Jurchen tribes were united by Akuta, who in 1114 led an uprising against the Khitans that resulted in the formation of the independent Chin state (1115–1234), which was eventually destroyed by the Mongol conquerors. Under the Mongols, the Jurchens once again split up into several tribal groups and until the 16th century played a minor role in the history of Eastern Asia.

At the end of the 16th century a tribal elder named Nurhachi emerged from the Chienchou Jurchens, whose designation is derived from the area they inhabited. Between 1583 and 1625 he managed to unite the Chienchou tribes and several other tribes, which were subsequently known as the Manchus.

KALGAN (also Changchiak'ou), a city in North China, in Hopeh Province, in the valley of the Yang Ho (Huang Ho basin). Population, 1 million (1970). Kalgan is a highway junction and has a station on the Chingpao Railroad, which runs from Peking to Pao-t'ou. Industry includes ferrous metallurgy (at the Lunyang Metallurgical Combine) and machine building (the production of mining equipment, geological prospecting instruments, and ball bearings); the city also has a viscose factory and food-processing and glass enterprises. Iron ore is extracted at the Lunyang deposit near the city, and hard coal is also mined nearby. [29–534–2]

KEY JOINT, a coupling between a shaft and a part fitted on the shaft, effected by means of a machine key. Axial slots are required in order to seat the key on the shaft and in the part. Keys may have an interference fit (tightly seated) or a keying fit. The former group includes tangent, tapered sunk, tapered flat, and saddle types; sunk keys of uniform cross section and Woodruff keys have a keying fit (Figure 1). Keys having an interference fit transmit both peripheral and axial forces; those having a keying fit transmit only peripheral force. Interference-fit keys shift the

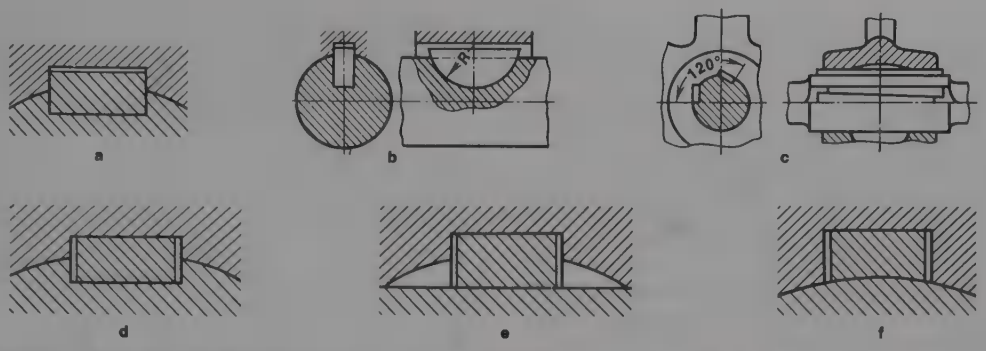

Figure 1. Key joints: (a) sunk key of uniform cross section, (b) Woodruff key, (c) tangent key, (d) tapered sunk key, (e) tapered flat key, (f) saddle key

center of gravity of the part on the shaft by an amount equal to the seating clearance; this usually results in a skewing of the part, which is the principal reason such keys have limited application.

Sunk keys of uniform cross section and Woodruff keys are the most widely used types; tangent keys are used in heavy machine building. Sunk keys of uniform cross section are seated in the shaft to half their height, and they have narrow faces (Figure 1,a). They can be used under a part that is slipped onto the shaft, in which case the key may be attached either to the shaft or to the part. The portion of a Woodruff key (Figure 1,b) seated in a shaft has a semicircular section. When torques are substantial, two or more keys are positioned along the axis of the shaft or around the periphery. Tangent keys (Figure 1,c) are used to transmit substantial torques that vary in value or direction. They consist of two single-taper wedges having the same taper (1 : 100) and narrow faces. Two keys are inserted, since the interference in the coupling is created in a peripheral direction. Tapered interference-fit keys are less often used; they may take the form of sunk keys (Figure 1,d) or flat keys (Figure 1,e); saddle keys (Figure 1,f) may also be used. When flat keys are used, a segmental groove is machined on the shaft; during a sudden increase in load, a flat key slips along the shaft, thereby cushioning the shock. Saddle keys are used to transmit relatively small torques.

S. N. POZDNIAKOV [29–1405–4]

KEYWAY-MILLING MACHINE, a metal-cutting machine tool for cutting sunk keyways of uniform cross section or Woodruff keyways in shafts. When an end cutter is used to mill a sunk keyway of uniform cross section, the machine's spindle carriage undergoes a reciprocating motion, thus providing longitudinal feed, while the tail spindle feeds to the cutting depth. Circular grooving cutters are used for Woodruff keyways. Some machines use both types of cutters to cut two keyways simultaneously. [29–1406–1]

KID LEATHER, a chrome-tanned leather made from goatskin. The best types of kid leather are obtained from the skins of young goats from stock bred for milk or for both milk and meat. Kid leather has attractive grain and exhibits considerable tensile strength (as much as 50 meganewtons per sq m). Kid leather is considered the highest quality material for the manufacture of shoe uppers: it is durable yet thin, soft, pliable, and attractive.

[29–1069–4]

KINGBOLTS AND KINGPINS (in Russian, *shkvoren'*). The pivot of a hinge joint between parts in transportation vehicles is called a kingbolt or a kingpin. Depending on context, the Russian word *shkvoren'* may mean either "kingbolt" or "kingpin."

In diesel locomotives, electric locomotives, and railroad cars, kingbolts are used, for example, to connect the wheeled trucks with one another or with the vehicle frame. A kingbolt is a vertical bolt.

In motor vehicles, kingpins are used to connect the front axle or, in the case of independent front suspension, the front-wheel supports with the steering knuckles, from which the steering spindles for the front wheels project. Kingpins are usually rigidly attached to the axle or the front-wheel supports and are inclined in two vertical planes to improve the steerability and stability of a motor vehicle and also to provide the proper wheel geometry, which affects the tires.

Kingbolts and kingpins are made of steel. [29–1253–5]

KJELLÉN, RUDOLF. Born June 13, 1864, in Torsø, in the *län* (county) of Skaraborg; died Nov. 14, 1922, in Uppsala. Swedish political figure and sociologist.

The son of a priest, Kjellén graduated from the University of Uppsala in 1883 and received the degree of doctor of sciences in 1890. From 1891 to 1916 he taught political science at the higher school of Göteborg, where he became a professor in 1901. In 1916 he began teaching at the University of Uppsala. He was a member of the Riksdag from 1905 to 1908 and again from 1911 to 1917.

Kjellén coined the term "geopolitics" and was an early proponent of the reactionary theory of that name, which defines the state as a geographic and biological organism that naturally seeks to expand. He was an ideologist of Swedish conservatism, a chauvinist, a Germanophile, and a militarist. Kjellén was, objectively speaking, among those who inspired the ideas of the German Nazis.

KJELLGREN, JOSEF. Born Nov. 13, 1907, in Mörkö, Södermanland; died Apr. 8, 1948, in Stockholm. Swedish writer.

Kjellgren first published his writings in workers' newspapers beginning in the second half of the 1920's. He joined the Swedish division of Clarté in 1928. Kjellgren used social motifs in his very first poetry collection, *The Light of the Beacon* (1931). He condemned fascism in the poetry collection *The West* (1933), the short-story collection *Gunshot Hole at the Waterline* (1936), and the play *The Unknown Swedish Soldier* (1938). Kjellgren developed the theme of international worker solidarity in the travel notes *Across Europe Without a Penny in My Pocket* (1930) and the collection of poems and essays *On the Banks of the Thames* (1937).

Kjellgren wrote "novels of the collective," for example, *People Around the Bridge* (1935; Russian translation, 1938) and the trilogy consisting of *The Emerald* (1939), *The Gold Chain* (1940), and *Men's Friendship* (1947). In *People Around the Bridge* he depicted the working class in the style of socialist realism and used a Communist as his hero. Kjellgren also wrote children's books. Many of his works reveal elements of expressionism.

LABOR ECONOMICS, in the USSR, the branch of economic science that studies the social organization of labor (hiring practices, cooperation and division of labor, distribution of the social product, and reproduction of labor power).

Labor economics studies the theoretical principles and objective economic laws that determine the most rational use of social labor at the various levels represented by the enterprise, the branch, and the national economy as a whole; it devises specific techniques to ensure the scientifically justified organization and planning of labor in socialist society; and it analyzes the basic differences between the socialist and the capitalist organization of labor, the superiority of socialism in this area, and the features that distinguish the organization of labor at different stages of communist construction.

Among the pressing issues of labor economics are (1) the development of methods ensuring a more effective coupling of material and moral incentives to increase production efficiency, (2) higher labor productivity, (3) better product quality, and (4) economical utilization of material resources. Problems that are an important concern of labor economics are those related to the wages of workers in the national economy—namely, improving the wage rate system as the basis of state regulation of wages, improving the system of bonuses for workers and office employees, and instituting a more efficient system of wage payments to kolkhoz workers.

Labor economics is related to various technical and economic sciences—the latter category including national economic planning, statistics, and finance. The scientific and practical recommendations of labor economics provide the foundation for a common methodological approach to such questions as national economic planning and labor accounting. At the same time, labor economics is based on the data of branch disciplines, such as industrial and construction economics; it resolves internal production problems through the extensive use of data pertaining to the technical implementation of labor rates, and it applies the conclusions and methods of the sociology of labor and labor statistics.

A considerable proportion of the problems related to the scientific organization of labor—whether in an enterprise, institution, or branch—fall within the province of labor economics. The scientific organization of labor constitutes a separate field of study. Many of the questions arising in labor economics are resolved on the basis of conclusions drawn from the biological disciplines—specifically, physiology, occupational hygiene, and labor psychology.

Labor economics interacts to a significant degree with labor law, which regulates the juridical labor relations of workers and employees. The labor law provides for certain economic relations that are studied by labor economics (for example, the extent of workers' participation in collective work, length of time allotted to work and to leisure, labor discipline, labor safety, and special measures for the protection of working women and youth).

Research studies in the area of labor economics are carried out in the academic institutions, in the scientific institutions of the various branches, in the higher educational institutions throughout the country, and in various subdivisions of the institutes of the Academy of Sciences of the USSR and of the Union republics. The results of labor economics research are extensively utilized by planning and management bodies for production planning, design, organization, and management. Research studies in labor economics are published in the journals *Sotsialisticheskii trud, Voprosy ekonomiki, Planovoe khoziaistvo*, and *Ekonomicheskie nauki*. All the central scientific and technical journals of the various branches of the national economy have special sections devoted to the labor economics of the particular branch.

L. S. KHEIFETS [29–1808–1]

LADLE CAR, a welded steel ladle mounted on a railway car for transporting molten pig iron to the mixer in a steel-smelting plant or to a casting machine. The interior is lined with refractory brick. Locomotive traction is used to move the car; five or six cars are coupled together. The most common ladle cars used in the USSR have capacities of 100 and 140 tons. [29–734–1]

LANDING GEAR, the parts of an airplane that make possible maneuvering on the ground or the deck of an aircraft carrier and that soften the landing shock. The principal components of an airplane's landing gear are the shock struts, the wheels—pneumatic tires equipped with brakes to reduce the length of the landing run—and a system of drag struts, which connect the shock struts and wheels to the wings and the fuselage and which absorb the drag load and the impulsive drag load.

Before 1939, tail-wheel landing gear designs were the type most widely used. During World War II and in the postwar years, the tricycle landing gear came into common use. Such an undercarriage has two main struts aft of the aircraft's center of gravity and a nose gear that carries 10–15 percent of the airplane's weight and serves as a third support point. Although the landing gear in most airplanes is drawn up into the fuselage or the wings after takeoff, the landing gear in small planes is usually not retractable. It is most often of a simple design that allows replacement of the wheels with skis or pontoons for flights in regions with expansive water areas. Heavy airplanes sometimes have landing gear with 20–30 wheels fitted in bogies.

S. IA. MAKAROV [29–873–6]

LAND VALUATION, the determination of the comparative worth of land as a means of agricultural production, based on the land's natural and enhanced fertility, on the various natural and economic conditions of the region in which it is located, and on the lay of the land.

Carried out primarily through classification of soils according to agricultural-production indexes, valuation of land on a point scale gives an idea of what the land is like and what demands can be made of a farm with respect to such matters as income, yield, and taxation. Under capitalism, land valuation has a decisive influence on the price of land and on rent. In the USSR, valuation of land is provided for in the Basic Principles of Land Legislation of the USSR and the Union Republics (1968). Land-valuation data are recorded in the land cadastre. [29–1828–2]

LAPAROTOMY, a surgical incision in the abdominal cavity. Although laparotomy was even known to ancient physicians, it was seldom used before the introduction of antisepsis and asepsis because of the danger of infection. It provides access to the organs of the abdominal cavity and lesser pelvis and is performed in cases of inflammation and tumors, as well as in cases of stomach wounds and other injuries; it is sometimes used as an independent procedure for diagnostic purposes (celiotomy, or diagnostic laparotomy). It is sometimes combined with thoracotomy.

Laparotomy is performed using a transverse, vertical, or oblique incision. The purpose of the surgical procedure determines the patient's position on the operating table—completely horizontal or with the head of the table raised or lowered or a bolster placed under the small of the back. Preoperative preparation of the patient and the anesthesia used depend on the nature of the procedure and the patient's condition. The abdominal cavity is closed by layer-by-layer suturing of the anterior abdominal wall, with insertion of drains if required. [29–690–2]

LAPWING (*Vanellus vanellus*), also green plover or pewit, a bird of the family Chardriidae of the suborder Limicolae. The body measures 30 cm in length, and the weight is approximately 200 g. The upper parts and breast are greenish, with a purple sheen. The lapwing is distributed in Europe and Asia. In the USSR it is found from the western border to Primor'e Krai; in Siberia it occurs only in the south. In the winter it is commonly found in Middle Asia and Transcaucasia. Lapwings nest in grassy marshes, pasturelands, or fields. The clutch contains four eggs, which are incubated primarily by the female for 27 to 29 days. The diet includes insects and other small invertebrates, as well as seeds.

[29–545–5]

LARD, the subcutaneous fatty tissue of hogs. The protein content of lard amounts to as much as 1.4 percent, and the fat content, to more than 92 percent. The proteins are primarily incomplete proteins, such as elastin and collagen. Most of the fatty acids making up the fat are unsaturated, for example, oleinic and linoleic acids. The principal saturated fatty acids are palmatic and stearic acids. Lard is used as part of sausage stuffings; it is also eaten in salted or salted and smoked form, for example, Hungarian bacon. [29–1394–2]

LARIDAE, a family of birds of the order Charadriiformes. The body length ranges from 20 cm (least tern [*Sterna albifrons*]) to 76 cm (glaucous gull [*Larus hyperboreus*]). Some species have a rather thin, straight, pointed bill, while other species have a more powerful, slightly decurved bill, with a prominence on the mandible. The bill is often brightly colored. The long and pointed wings are adapted for prolonged flight over water; some species can soar and glide. The legs are short or of moderate length; the feet are webbed, sometimes deeply lobed. The Laridae are good swimmers; they sometimes dive after their prey by simply plunging into the water. The plumage is thick and waterproof. It is alike in males and females but differs considerably depending on the season and the bird's age. The adult plumage is acquired in the third to fourth year of life. White, gray, and black predominate in the coloration.

All the Laridae are closely tied to the water, inhabiting the shores of oceans, seas, rivers, and open and overgrown lakes. They are predominantly gregarious birds, living in flocks. They nest in colonies and on sandbars, cliffs, broken reeds, and floating plants; some nest in trees, shrubs, and even burrows. The clutch contains one to four solid-colored or spotted eggs. Both the male and female incubate the eggs and feed the young, which are covered with a thick down. The young leave the nest very soon after hatching but remain close to it; the parents feed them until they begin to fly.

The Laridae are distributed all over the world. Many species migrate, but some winter near their nesting sites in ice-free bodies of water, sometimes very far north; some make long migratory flights. The diet includes fish, marine and freshwater invertebrates, carrion, and waste products of the fishing industry. Some species are beneficial to man, for they fly over fields and catch rodents and insects; other species are harmful, since they kill fish or destroy the nests and kill the young of commercially useful birds, such as eiders and other ducks.

The family comprises 82 species, grouped into two subfamilies: Sterninae (terns) and Larinae (gulls). Of the latter, 20 species nest in the USSR, including the ivory gull (*Pagophila eburnea*), Ross's gull (*Rhodostethia rosea*), the fork-tailed, or Sabine's, gull (*Xema sabini*), the herring gull (*Larus argentatus*), the short-billed, or mew, gull (*Larus canus*), the black-headed gull (*Larus ridibundus*), the Mediterranean gull (*Larus melanocephalus*), the lesser black-backed gull (*Larus fuscus*), and the kittiwake (*Rissa tridactyla*). (*See also* TERN.)

LATHYRUS, a genus of annual and perennial herbaceous plants of the family Leguminosae. The four-angled main stalks are trailing, clinging, climbing, or—less commonly—erect. Their height is 15–20 cm (to 1.5 m). The lateral branches rapidly overtake the main stem in length. The leaves are uniparipinnate or, less commonly, bijugate to quadrijugate; they are oblong-lanceolate or lanceolate. The inflorescence contains one or, less often, two white, purple-violet, yellow, orange, lilac-blue, or pink flowers. The plants generally are self-pollinating. The fruit is a two-winged pod. Three groups are distinguished according to the color of the seeds and flowers (white, light, and dark) and according to the size of the seeds (large, small, and medium—lengths from 4 to 16 mm).

There are more than 100 species, distributed in Europe, Asia, and Northwest Africa. The USSR has 50 species. Most species are forage plants. *Lathyrus* is cultivated in many countries. In the USSR small areas are planted with the perennial meadow pea (*L. pratensis*) and the annual field pea (*L. sativus*), flat podder (*L. cicera*), and Tangier pea (*L. tangitanus*). Most widely distributed is the field pea, which is cultivated as a grain crop in the Northern Caucasus, Transcaucasia, the forest-steppe regions of the Ukrainian SSR, the central regions of the RSFSR, Western Siberia, and Middle Asia. The field pea is also grown for green feed and hay in more northern areas. The plant grows well in various soils; it is drought resistant and can withstand temperatures to −8°C. The vegetative period lasts 100 to 115 days in the temperate zone. The seeds are sown at the same time as early spring crops, using the wide-row (for grain) or broadcast (for green feed or hay) method. The sowing rate for pure plantings is 130–160 kg per hectare (ha); the sowing depth is 4–8 cm. The field pea is harvested for grain when 75 percent of the beans turn yellow, for green feed when the plants are in early bloom, and for hay when the beans first develop. In humid years it may yield a good aftercrop and, in a mixture with Sudan grass, a second cutting. The harvest from 1 ha is 220–230 quintals of green feed in pure plantings, 30–35 quintals of hay, and 15–20 quintals of grain.

There are 108.2 feed units and 20.5 kg of digestible protein in 100 kg of the grain and 15.8 feed units and 3.6 kg of digestible protein in 100 kg of green matter. Green feed is readily eaten by cattle and swine, and the hay by cattle and sheep. The meadow pea is particularly leafy. It is cultivated as green feed and hay in the forest, forest-steppe, and steppe zones and the mountain regions of the Caucasus and Middle Asia. The yield of hay is 25–35 quintals per ha. The plant is eaten readily by sheep and horses but not as well by cattle.

A. P. MOVSISIANTS [29–602–3]

LATITUDE, one of the coordinates in numerous systems of spherical coordinates that determine the position of points on the earth's surface (*see* GEOGRAPHIC COORDINATES and COORDINATES [in geodesy]), on the celestial sphere (*see* CELESTIAL COORDINATES), or on the surface of the sun, moon, and planets (*see* HELIOCENTRIC COORDINATES; SELENOGRAPHIC COORDINATES; and PLANETOGRAPHIC COORDINATES).

For the earth, a distinction is made between astronomical latitude and geodetic latitude (or geographical latitude), depending on the method of determination. The astronomical latitude ϕ of a point on the surface of the earth is equal to the angle between a plumb line (normal to the geoid) to the point and the plane of the earth's equator. It is also equal to the height of the pole of the earth above the horizon and is considered to be positive in the northern hemisphere and negative in the southern hemisphere. The latitude of points on the equator is 0°; the latitude of the north pole is +90°, and that of the south pole, −90°. Lines with the same values of ϕ are parallels.

Unlike astronomical latitude, which is determined from astronomical observations, geodetic latitude is computed on the basis of measurements on the earth's surface, for example, by the triangulation method, taken between the point being measured and a certain starting point. Geodetic latitude is equal to the angle formed by the normal to the reference ellipsoid passing through the given point and the plane of its equator.

The geocentric latitude ϕ' is equal to the angle between the radius drawn from the center of the earth's ellipsoid to the given point and the plane of the equator. There is a relationship between astronomical latitude and geocentric latitude: $\tan \phi' = (b/a)^2 \tan \phi$, where a is the semimajor axis of the earth's ellipsoid and b is the semiminor axis. The largest difference between ϕ and ϕ' occurs when $\phi = 45°$ ($\triangle\phi \simeq 11'5$); at the equator and the poles, $\triangle\phi = 0$.

In geodesy, the reduced latitude u is also used, whose values lie between ϕ and ϕ' and are determined by the formula $\tan u = (b/a) \tan \phi$.

A. A. MIKHAILOV [29–1235–1]

LATITUDE, GEOMAGNETIC, the angle ϕ, which is the complement (to 90°) of the angle formed by the axis of a uniformly magnetized earth (the axis of the earth's magnetic dipole) and a

radius vector drawn from the center of the earth to a given point on its surface. Geomagnetic latitude ranges from $+90°$ at the geomagnetic pole in the northern hemisphere to $-90°$ at the pole in the southern hemisphere.

The concept of geomagnetic latitude is used in studying various geophysical phenomena. However, for detailed investigations of the latitudinal distribution of the aurora borealis, magnetic and ionospheric disturbances, the absorption of cosmic radiation, and similar phenomena, the concept of corrected geomagnetic latitude is used. Its calculation considers both the dipole members and the higher terms in the expansion of the earth's potential in a series of spherical harmonics. (*See* TERRESTRIAL MAGNETISM.)

REFERENCE
Akasafu, S. I., and S. Chapman. *Solnechno-zemnaia fizika*, part 1. Moscow, 1974. (Translated from English.) [29–1236–3]

LATITUDE, MAGNETIC, the angle ψ, determined from the equations $\tan \psi = (1/2) \tan J$, where J is the magnetic inclination (or magnetic dip). Magnetic latitude ranges from 0°, at the magnetic equator, to 90°, at the north and, correspondingly, south magnetic poles. The concept of magnetic latitude is used in all research involving the study of the physics of the magnetosphere, in particular, in the analysis of geophysical phenomena at magnetically conjugate points on the earth's surface (points lying on one line of force of the geomagnetic field). [29–1236–4]

LATITUDE STATION, a specialized astronomical observatory that studies the regularities governing the phenomenon of variability of geographic latitudes.

Latitude stations are equipped with instruments for the regular determination of the station's geographic latitude on the basis of astronomical observations. The combined mathematical processing of the observations made at several latitude stations makes it possible to determine the position of the earth's geographic pole on the earth's surface at a series of moments in time and thus construct a curve of polar motion, called a polhode. The chief instruments used at latitude stations are a zenith telescope, a photographic zenith telescope, and a prismatic astrolabe.

Included within the International Polar Motion Service are five latitude stations with similar instruments, situated on the same geographic parallel—39°08′—and more or less evenly spaced by longitude; one of these stations is in the Soviet Union—the Ulugbek Latitude Station of the Academy of Sciences of the Uzbek SSR, located in Kitab. At the same time, about 50 astronomical observatories in different countries are conducting systematic observations of variations in latitude for the immediate computation of the coordinates of the poles at the International Time Bureau and the introduction of necessary corrections in the world time scale.

Of particular scientific value for the study of polar motions have been the long-term observations with two high-precision zenith telescopes at the Pulkovo Observatory of the Academy of Sciences of the USSR; the lengthy series of observations with the zenith telescopes of the Greenwich Observatory in Great Britain; the series of around-the-clock observations of two bright stars in Poltava, USSR, conducted over a period of 40 years; the observations with the photographic zenith telescope conducted since 1915 in Washington, D.C., (United States); and the observations with two zenith telescopes, a photographic zenith telescope, and a prismatic astrolabe conducted at Misuzawa, Japan. Laser range-finding observations by artificial earth satellites began to be carried out in the mid-1970's to determine the position of the poles of the earth. L. V. RYKHLOVA [29–1236–7]

LEAF CAST, a disease of coniferous needles caused by pathogenic fungi. There are three types of leaf cast. The most common is caused by ascomycetes of the genus *Lophodermium*. A second type is caused by the ascomycete *Phacidium infestans*, and a third by the imperfect fungi of the genus *Meria*.

Symptoms of leaf cast are yellowing and then browning and falling of the needles. In leaf cast caused by *Phacidium infestans*, a white gossamer-like mycelium appears in the spring; the needles turn brown, and by autumn they are ash-gray. Leaf cast is especially dangerous in tree nurseries. Control measures include removal and burning of dead plants and fallen needles, pinching off diseased needles, and spraying seedlings (before the formation of the snowy covering) with a suspension of zineb or other fungicides.

LENS (lentil), a genus of annual herbs of the family Leguminosae. The erect or partly climbing stem is 20–55 cm tall. The compound even-pinnate leaves have three to eight pairs of narrow leaflets, which end in short bristles measuring 1–60 mm long. The small white, pink, or violet-blue flowers are distributed singly or in groups of two or three on the axillary peduncle. The fruit is a pod; the flat or protuberant seeds are multicolored, monochromatic, or in patterns. The common lentil (*L. culinaris*) is classified into two groups according to the size of the seeds: the large-seeded plate-like group has a seed diameter of 5.5–9 mm, and the small-seeded group has a seed diameter of 2–5.5 mm.

There are five species in the Mediterranean region, Asia Minor, Transcaucasia, and Middle Asia. The common lentil, the only cultivated species, is distributed in many countries of Europe, Asia, and North Africa. In the USSR it is found in the southern European region, the Volga region, and Middle Asia. The plant is a food and feed crop.

Lentils are a spring crop, with a vegetative period of 75 to 115 days. The plants are relatively drought resistant, and the shoots can withstand brief frosts to $-5°C$. The best soils are loose loams and sandy loams rich in lime. The feed is poor on very acidic and solonetzic soils. In crop rotation, lentils follow winter and root crops. Like other legumes, lentils enrich the soil with nitrogen and are good predecessors for subsequent crops. Seeds are sown in rows spaced 15 cm apart. Phosphorus fertilizer (40–80 kg/ha of P_2O_5) and potassium fertilizer (60–100 kg/ha of K_2O) are applied during late-fall plowing or during spring cultivation. Granulated superphosphate is used during seeding. Harvesting operations are begun when the beans on the lower and middle section of the plant begin to ripen and the seeds of the upper beans finish ripening in swathes. Combines, reapers, and hay cutters are used for harvesting. When the swathes are dry, they are threshed by combines and grain threshers.

Mature lentil seeds contain 23–32 percent protein (in dry matter), as much as 60 percent starch, and as much as 2.5 percent fat; they also contain vitamins B_1 and B_2. The seeds of large-seeded lentils are used in the production of groats and flour for bread, sausage, confectioneries, and canned goods. The seeds of small-seeded lentils, the green mass, the chaff, and the straw are fed to agricultural animals. One hundred kg of grain contains 120 feed units and 21 kg of digestible protein. Ten varieties of lentils have been regionalized in the USSR, including Petrovskaia-4/105, Talinskaia-6, Penzenskaia-14, and Petrovskaia lubileinaia.

In 1976 the world area under lentil cultivation was about 1.8 million ha, the gross grain yield was 1.2 million tons, and the average yield was 6.8 quintals per ha. In the USSR lentils are grown on small areas; in 1976 the crop occupied 35,700 ha.

LENTICEL, a loose lens-shaped mass of cells in the periderm. Lenticels appear on the trunks of perennial limbs and, sometimes, on the roots of woody plants in the form of protuberances. Lenticel formation is activated by phellogen; the lenticels usually form beneath the stomata. Lenticels permit the exchange of gases. [29–506–2]

LEONTOPODIUM (edelweiss), a genus of perennial plants of the family Compositae. The heads are crowded together into dense tufts or complex cymes. Sometimes the heads are solitary. The tufts or cymes are usually surrounded by feltlike, extended terminal leaves, which are arranged in a characteristic star form.

There are about 30 species (according to other data, as many as 50), distributed throughout Eurasia except for the Caucasus and

Western Asia. The USSR has six to eight species in the Far East and Siberia, two species in Middle Asia, and one species in the Carpathians. The plants grow mainly in the mountain-steppe and high-mountain belts with elevations to 5,000 m. The most common species is the alpine edelweiss (*L. alpinum*), whose snow-white woolly terminal leaves form a regular many-rayed star. Gathered widely for its exceptional beauty, the plant almost became extinct. It was listed in the *Red Data Book* and is now a protected species.

LEVEL WIDTH, the uncertainty in the energy of a quantum-mechanical system having discrete energy levels $\mathcal{E}_k$ in a state that is not strictly stationary. The system may be an atom, a molecule, or an atomic nucleus.

The level width $\Delta\mathcal{E}_k$ characterizes the broadening of an energy level and the energy spread in the level. It depends on the mean life of a system in a given energy state—that is, on the lifetime τ_k of the system in the level—and, in accordance with the uncertainty relation for energy and time, is given by the expression $\Delta\mathcal{E}_k \approx \hbar/\tau_k$, where $\hbar$ is Planck's constant. For a stationary state of a system, $\tau_k = \infty$ and $\Delta\mathcal{E}_k = 0$. The lifetime τ_k and, consequently, the level width result from the possibility of quantum transitions of the system to states of lower energy.

For a free system, such as a single atom, spontaneous radiative transitions from level $\mathcal{E}_k$ to lower-lying levels $\mathcal{E}_i$ ($\mathcal{E}_i < \mathcal{E}_k$) determine the radiation width, or the natural width, of the level: $(\Delta\mathcal{E}_k)_{\text{rad}} \approx \hbar A_k$, where $A_k = \Sigma_i A_{ki}$ is the total probability of spontaneous emission from level $\mathcal{E}_k$; A_{ki} is Einstein's coefficient for spontaneous emission. The broadening of an energy level may also be caused by spontaneous nonradiative transitions, for example, by the alpha decay of a radioactive atomic nucleus. The width of an energy level of an atom is very small in comparison with the energy of the level.

In other cases, the level width may become comparable to the level spacing. For example, the probability of quantum transitions in excited nuclei is determined by the emission of neutrons and is very high.

Any interactions that increase the probability of a transition of a system to other states result in additional broadening of the system's energy levels. The Stark broadening of the energy levels of an atom or ion in a plasma as a result of collisions with ions or electrons may be cited as an example. In the general case, the total level width is proportional to the sum of the probabilities of all possible transitions—both spontaneous transitions and transitions induced by various interactions—from a given energy level.

The level width determines the line width of a spectral line.

LIGHT-BEAM OSCILLOGRAPH, an instrument used for the visual observation and the automatic recording, by a photographic method, of physical processes that are periodic, aperiodic, or nonrecurrent. Examples of such processes include strain, temperature changes, pressure variations, and changes in rate. In the case of periodic processes, light-beam oscillographs are usable for repetition rates ranging from fractions of a hertz to 10–15 kilohertz. At the oscillograph input, a variation in a physical quantity that characterizes the process under investigation is converted by appropriate sensors into a proportional change in voltage or current.

A light-beam oscillograph (Figure 1) consists of the following: one or more mirror galvanometers, usually with a bifilar moving coil; an optical system; a recording medium, which may be either photosensitive paper or photographic film; a unit that moves the paper or film (not shown in Figure 1); and a device for visual observation.

The optical system forms and focuses a light beam and directs it to the galvanometer mirror. The beam is reflected from the mirror onto the sensitized film or paper, where it traces a curve that depicts the variation over time in the physical quantity under investigation. The time base of the curve is provided by the uniform movement of the recording medium in a direction perpendicular to the deflection of the light beam. The speed at which the recording medium moves in various light-beam oscillographs ranges from 1 to 10,000 mm/sec. The recorded curve is observed visually by means of a spherical mat screen, upon which impinges

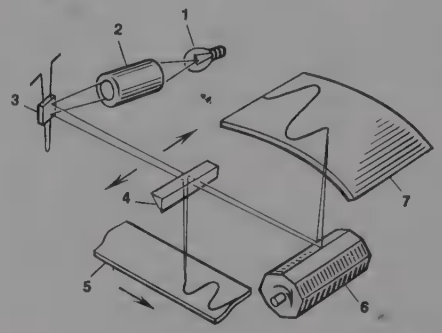

Figure 1. Diagram of the primary components of a light-beam oscillograph: (1) light source, (2) focusing objective, (3) mirror, (4) optical prism, (5) recording medium, (6) specular drum, (7) screen for visual observation

a portion of the light beam reflected from the mirror. The time base of the visually observed curve is provided by means of a uniformly rotating polyhedral specular drum. When the drum rotates, the light beam is reflected from its specular surfaces and periodically sweeps the screen. By adjusting the rotational speed of the drum, a stationary image of the curve may be obtained.

Multichannel light-beam oscillographs are used for the simultaneous recording of several physical quantities. Such oscillographs contain from four to 60 mirror galvanometers, which provide for the simultaneous recording of a corresponding number of curves.

Light-beam oscillographs are widely used in scientific research, laboratory experiments, and industrial testing.

LINCHPIN, a wedge-shaped rod that fits into a hole in a part and prevents another part from shifting to one side while fastened to the first part. The shape of a linchpin prevents the pin from falling out of the hole. Linchpins were used in horse-drawn vehicles to prevent the wheels from coming off the axle. They are used for unstrained joints between parts, for example, as safety pins in hand grenades. [29–128–2]

LINKAGE (in Russian, *sharnir*), a movable connection between two bodies. In a cylindrical linkage, the relative movement of the two bodies is rotation about an axis; in a spherical linkage, the relative movement is rotation about a point.

A cylindrical linkage in a mechanism is called a rotary kinematic pair. It consists of a journal rotating in either a simple bearing or a rolling-contact bearing.

A spherical linkage in a mechanism is referred to as a spherical kinematic pair. It may be either a ball and socket or a ball bearing. Such a linkage is difficult to manufacture. Therefore, it is often replaced by a universal joint, which consists of two or three cylindrical linkages that are connected in tandem and whose axes of rotation intersect at a single point. Various modifications of the universal joint may be used instead of a spherical linkage; such modifications differ in the number of intermediate links and in the type of kinematic pairs formed by the intermediate links.

A linkage may be exposed or enclosed. An enclosed linkage is protected from dust or sand by a housing and is used in machinery that operates in air with a high dust content.

Linkages are used not only in machine mechanisms but also in

building systems, such as trusses. In such systems, linkages are employed to relieve the components of bending stresses and to reduce thermal stresses. N. I. LEVITSKII [29–862–3]

LINKWORK (in Russian, *sharnirnyi mekhanizm*), a mechanism whose elements (links) form only rotating kinematic pairs (linkages).

Depending on the type of motion of the links, linkworks are classified as plane, spherical, and general three-dimensional. In plane linkworks the axes of the linkages are parallel, and all links therefore undergo plane-parallel motion. The simplest plane linkwork consists of four links and is called a four-bar linkage. In spherical linkworks the axes of the linkages intersect at a single point. The smallest number of links in a spherical linkwork also is four. A spherical four-link motion (Figure 1) is used, for example, in multipiston pumps and aircraft stabilizers. The Cardan mechanism is a particular case of the spherical four-bar motion, in which the axes of two rotating pairs are mutually perpendicular. In three-dimensional linkworks the axes of the rotating pairs cross at different angles. In the general case a three-dimensional linkwork should have at least seven links (a three-dimensional seven-bar motion). When certain relations between the linear and angular dimensions of the links are satisfied, however, the minimum number of links is reduced to four (for example, Bennett's mechanism). Three-dimensional linkworks find application in agricultural machinery and automatic machines used in food processing and light industry.

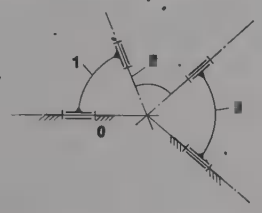

Figure 1. Spherical four-bar motion: (0) fixed link, (1), (2), and (3) movable links

Depending on the method used to define the required motion of a working link, linkworks are subdivided into positioning, guiding, and transmission mechanisms and mechanisms for interrupted motion. Positioning linkworks are designed to move a working link from one position to another; the number of defined positions is usually two, less often three or four. Such linkworks are used in metallurgical machines (such as tilters, tippers, and mechanisms for plugging tap holes) and in automatic machinery for the food-processing industry (for positioning working members of machines). Guiding linkworks are designed to move along a specified curve a single point of a link that does not form a kinematic pair with the stay. Linkworks that guide along the arc of a circle (circular guiding mechanisms) and straight-line mechanisms, such as the Chebyshev parallel motion, are the most widely used types. Linkworks are also used to shape parabolas and hyperbolas, such as the mechanisms for grinding the mirrors

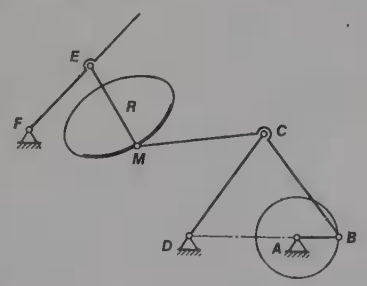

Figure 2. Linkwork for interrupted motion

of astronomical instruments. Transmission linkworks are designed to convert rotary motions according to a specific law. They act as mechanisms for reproducing a given function. In calculators, transmission linkworks are used to perform such mathematical operations as addition, multiplication, and raising to powers. Through special selection of the lengths of the links, it is possible to obtain an approximate reproduction of diverse functions. For example, when the function $y = f(x)$ is reproduced, the angles of rotation of one rotating link are proportional to the argument x, and the angles of rotation of the other are proportional to the function y.

Linkworks for interrupted motion are used in automatic machines to set in motion a working member that, after completing a specific operation, must remain stationary for some period of time while the other working members move. A diagram of a six-bar linkwork for interrupted motion is shown in Figure 2. The mechanism transforms the continuous motion of link AB into the motion of link EF with prolonged stops in a single position. The linkwork is based on the circular guiding mechanism $ABCD$, in which the lengths of the links are selected such that the trajectory of point M on the section marked by the heavy line on the diagram nearly coincides with the arc of a circle of radius R. As point M moves along the segment, link EF remains stationary if the length of link EM is equal to radius R and point E coincides with the center of the circle at this time. As point M moves along a different segment of the trajectory, link EF is shifted by some angle and returns to the stop position.

Linkworks are widely used in various fields of engineering because of their simplicity of manufacture and high reliability. Their shortcomings include relatively large size and the possible appearance of significant forces acting on the links at positions where the displacement of some center of a linkage subtends an angle close to 90° with the effective force. Furthermore, not all laws that may be required for the transformation of motion can be obtained by means of linkworks.

LISP (parasigmatism), the imperfect pronunciation of sibilants (z, s, ts, ʒ, tʃ, ʃ, ʃtʃ). It may be due to defective arrangement of the teeth (such as the presence of a gap between the front teeth), inadequate mobility of the tongue, partial deafness, or other cause. It sometimes occurs when the structure of the vocal apparatus is normal as a manifestation of underdeveloped speech. The afflicted person usually places the tip of the tongue between the front teeth when articulating sibilants, which results in the characteristic lisping sound. Logopedic methods are used to correct the defect. Surgery or the use of a prosthesis is sometimes indicated when there are structural anomalies of the vocal apparatus. [29–1133–1]

LITHUANIAN BLACK AND WHITE CATTLE, a breed of dairy and dairy-meat cattle. The Lithuanian Black and White was developed in the early 20th century by crossing local cattle with Ostfriesian, Swedish Black and White, Holstein-Friesian, and other breeds. The bulls weigh 850–1,000 kg, and cows, 500–550 kg. The average milk yield is 3,500–4,000 kg, and the largest yield is 12,550 kg. The fat content of the milk is 3.6–3.8 percent. The young fatten rapidly; by 15 months the bulls weigh 450 kg or more. The dressed yield is 58–60 percent. The breed is raised in the Lithuanian SSR. The purebred cattle are exported to other republics to improve local stock.

LOCATION THEORIES (also *Standort* theories), bourgeois theories of the most advantageous location for enterprises. Location theories were developed to determine the location (German, *Standort*) for a given enterprise that would ensure the minimum production costs or maximum profits for the owner. The expression "location (*Standort*) of an industrial enterprise" and the basic ideas of location theories as they apply to industry originated with the German economist W. Launhardt in 1888. The German economist A. Weber gave a more fully developed exposition of the theories in 1909. [29–1453–6]

LOCK, in navigation, a hydraulic engineering installation that is located between bodies of water with different levels and through which vessels or rafts pass. Locks are built on canals, at hydraulic

Figure 1. engineering complexes on rivers, and in seaports whose water area experiences large-amplitude tides.

A sketch of a lock was discovered in the papers of Leonardo da Vinci. Locks were first built in Western Europe in the 16th century and in Russia—on the Vyshnii Volok Water System—in the 18th century. In the USSR, many large locks have been constructed on numerous navigation canals, at reservoirs, and at hydraulic engineering complexes on the Volkhov, Dnieper, Svir', Volga, and Kama rivers. A substantial number of large locks have been built in Western Europe and in the USA, for example, on the Ohio, Mississippi, and St. Lawrence rivers.

A lock (Figure 1) consists of chambers, ends, and approaches. A lock chamber, in which vessels to be raised or lowered are held, is formed by two longitudinal walls and a floor. As a rule, the walls and floor are made of reinforced concrete. The chamber is sealed by metal gates located within the upstream and downstream ends. According to the number of successive chambers in a lock, a distinction is made between single locks and flights of locks. The number of chambers in a lock depends on the magnitude of the change in water level and on the relief of the terrain. To increase the traffic capacity of a lock, two or more lanes of chambers are built in tandem.

The main dimensions of lock chambers—that is, their length and width—are chosen when a lock is designed. They depend on the category of the waterway, the amount of freight expected to be handled on the waterway, and the size of the largest vessel, train, or convoy the lock is designed to accommodate at one time. The chambers of the largest locks are up to 33 m wide, up to 400 m long, and—in locks in seaports—from 5 to 15 m deep at the sea entrance. Lock chambers are filled or emptied in a prescribed time, from 5 to 15 min, by means of filling or emptying valves and a culvert system.

The ends of a lock are usually massive headworks. In addition to gates, which maintain the difference in water levels and permit vessels to pass through when the levels of adjacent pools are equalized, the ends contain sluice culverts, equipment for eliminating water turbulence, repair and emergency booms, equipment control mechanisms, and automatic control systems. The approaches to a lock's upstream and downstream ends comprise canals for sectors of a water area that contain both berthing facilities and facilities for mooring ships waiting to be locked and guiding structures for the safe entry of vessels into the lock.

The process of passing vessels through a lock, called lockage, consists in a sequence of operations that are carried out in accordance with commands issued from a control center. The operations include the opening and closing of gates and valves, the filling of the lock chambers with water, the emptying of the chambers, and the entry and departure of vessels. The number of lockages completed in a day during the continuous operation of a lock determines the traffic capacity of the lock.

LOCKING OF RIVERS, increasing the depth of rivers in individual sections by building a series of hydroengineering complexes that raise the water level above the natural level. Locks are built to facilitate navigation and the integrated use of water resources; in such cases the hydroengineering complexes built include structures to allow the passage of ships (*see* SHIP LIFTS AND INCLINED PLANES). Locks intended solely for navigation are part of low-head hydroengineering complexes with sectional dams whose head levels do not allow the river to leave its channel; they are used where the floodplain is built-up or is valuable for agriculture, for example, on the Moscow, Oka, and Don rivers.

When the water resources of rivers are subject to integrated use, such as the combined use for purposes of power generation and navigation with regulation of river flow by reservoirs, locks are built as the transportation part of the complex and must provide a specified navigation depth on the approaches to the hydroengineering complexes located upstream.

LOCKSTITCH, in sewing, the portion of stitched thread between two punctures of the needle, produced by means of a shuttle. In lockstitches the interlacing of the threads normally takes place in the material; the form of the stitching on the front and back sides is identical.

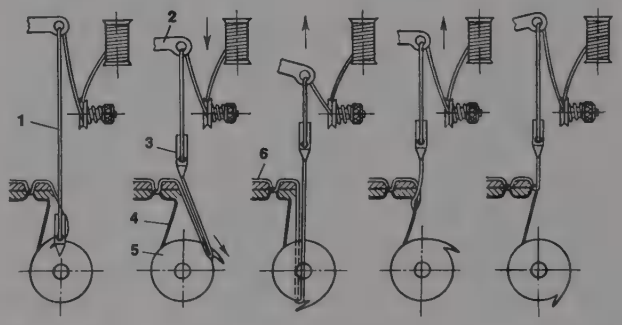

Figure 1. Sequence in the formation of a lockstitch by drawing a loop around a bobbin: (1) needle thread, (2) thread tensioner, (3) eye-pointed needle, (4) bobbin thread, (5) shuttle, (6) material being sewn

Lockstitching usually involves two threads; three threads are used when working with two needles and one shuttle. Lockstitches do not permit much stretching along the stitching and are therefore unsuitable for elastic materials, for example, in knitwear. They are not subject to raveling. Their principal drawback is the loss in strength in the needle thread, since the same portion of the thread passes through the eye of the needle many times while forming the stitches (see Figure 1). [29–137–1]

MAN, the most advanced form of life on earth and the subject of social and historical activity and culture. Various branches of knowledge, including sociology, psychology, physiology, pedagogy, and medicine, are devoted to the study of man. By reworking the various types of data furnished by these sciences, philosophy interprets and gives meaning to their findings.

The question of man's nature (essence), his origin and purpose, and his place in the world has been one of the fundamental problems in the history of philosophical thought. In ancient Chinese, Indian, and Greek philosophy man was perceived as being

a part of the cosmos, of a unified supratemporal "order" and "system" of existence ("nature"). He was viewed as a "microcosm" (Democritus), as a reflection and symbol of the universe, the macrocosm, which was in turn interpreted anthropomorphically as a living being possessing a soul. Man was thought to contain all of the principal elements of the cosmos and to consist of a body and soul (spirit), which were interpreted either as two aspects of a single reality (Aristotelianism) or as two different substances (Platonism). In the doctrine of the transmigration of souls, which was developed in Indian philosophy, the boundary between living beings (plants, animals, men, gods) is not fixed; only man, however, strives for "release" from the fetters of empirical existence and its law of *karma-samsara*. According to the Vedanta, man's specific principle is *atman* (soul, spirit, "self"), which is essentially identical with the universal spiritual principle, or *brahman*. Aristotle's philosophy expressed the view, characteristic of classical philosophy, that man was a living being endowed with spirit and reason (a "rational soul" as opposed to a sensitive or vegetative soul) and with the capacity for social life.

In Christianity, the biblical concept of man as the "image and likeness of god," divided against himself after his fall from grace, is combined with the doctrine of the union of the divine and the human in the person of Christ, enabling every man to commune with the divine. (The term "superman"—Latin *superhumanus*—crystallized in Christian tradition.) Medieval philosophy advanced the concept of personality as distinct from psychophysical individuality and not reducible to some universal "nature" or substance (whether corporeal or spiritual), defining personality as a unique relationship (Richard of St. Victor, 12th century).

The Renaissance was pervaded by a fervent belief in man's autonomy and his boundless creative capacities (Pico della Mirandola). The specific nature of man's sphere of existence was acutely felt by such Renaissance thinkers as Nicholas of Cusa (*On Conjecture*, II, 14). Descartes's idea of thought as the only reliable testimony of human existence ("I think, therefore I am") formed the basis of a new European rationalism that perceived man's uniqueness and essence in his ability to think and reason. The Cartesian dualism of body and soul long determined the kinds of questions raised in anthropology. The body was considered an automaton, a machine common to man and animals (J. de La Mettrie, *L'Homme machine*), and the soul was identified with consciousness. Benjamin Franklin defined man as "a tool-making animal."

Kant regarded What is man? as the fundamental question of philosophy. Proceeding from the dualistic concept of man as a being who belongs to two different worlds, that of natural necessity and that of moral freedom, Kant divided anthropology into physiological and pragmatic spheres: the former investigates "how nature affects man," and the latter studies "what man, as a being possessed of free will, makes or can and must make of himself" (*Soch.*, vol. 6, Moscow, 1966, p. 351).

Rejecting both Cartesian rationalism and the sensationalist empiricism of the 17th and 18th centuries, German philosophy of the late 18th and early 19th centuries revived the Renaissance conception of man as a living totality (J. G. Herder, J. W. von Goethe, romantic nature philosophy). Herder described man as the first being emancipated by nature. Man's sense organs and physical structure, in contrast to those of animals, are not specialized and are more indefinite, which is the source of man's particular advantage: he must mold himself, creating culture in the process. Herder, the Romanticists, and Hegel developed the idea of the historical nature of human existence; Novalis called history applied anthropology. In German classical philosophy man was perceived as the subject of spiritual activity, creating the world of culture, and as the bearer of a universally significant consciousness and a universal ideal principle, namely spirit and reason. Criticizing these ideas of German idealism, L. Feuerbach effected an anthropological reorientation of philosophy. At the center he placed man, defined as a sensible-corporeal being, as the meeting of the concrete "I" and "thou." In Russia the anthropological principle was developed by N. G. Chernyshevskii.

Such noncognitive capacities and powers as feeling and will became paramount in the irrationalist conceptions of man that emerged in the 19th and 20th centuries. According to F. Nietzsche, it is the interplay of vital forces and passions that determines man, and not consciousness and reason. S. Kierkegaard gave primacy to the act of free will by which man "gives birth to himself," to the choice by which the individual—that is, a spontaneous natural being—becomes a personality, a spiritual, self-determining entity. The question of personality is central to the conception of man in personalism and existentialism, which hold that man cannot be reduced to some sort of "essence," whether biological, psychological, social, or spiritual. Rejecting the social nature of personality, existentialism and personalism differentiate between and oppose the concepts of individuality and personality, viewing the former as part of a natural and social totality and the latter as a unique spiritual self-determination (*Existenz*). Dilthey's "philosophy of life" and Husserl's phenomenology paved the way for the emergence of philosophical anthropology as a distinct trend in 20th-century German philosophy, expounded principally by M. Scheler, H. Plessner, A. Gehlen, and E. Rothacker (*Kulturanthropologie*). The naturalist approach to man is characteristic both of exponents of traditional Freudianism and of many 20th-century naturalists in the West.

IU. N. POPOV

Rejecting the idealist and naturalist conceptions of man, Marxism undertook to explain man's natural and social aspects on the basis of dialectical-materialist monism. Marxism begins by treating man as a derivative of society, as the product and subject of social labor. Marx wrote that "the essence of man is no abstraction inherent in each separate individual. In its reality it is the ensemble of the social relations" (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 3, p. 3).

The Marxist analysis of the question of man is predicated on the discovery of the social essence and concrete historical determination of his consciousness and activity, on knowledge of the historical forms of man's existence and way of life. It also presupposes a disclosure of the relationship between man's social and biological aspects.

Man's social history was preceded by his natural prehistory: the worklike activity of the anthropoid apes, the development of gregarious relations among the higher animals, and the development of acoustic and motor means of communication. According to Marxism, the determining factor in man's development from these precursors was labor, whose origin marked the transition from anthropoid apes to man (F. Engels, *ibid.*, vol. 20, pp. 489–90). Animals cannot fundamentally alter their living conditions; they adapt to their environment, which determines their way of life. Man, on the other hand, does not simply adapt to prevailing conditions. By uniting in joint labor man transforms these conditions to suit his constantly growing needs, thereby creating a world of material and spiritual culture. Culture is created by man to the same extent that man himself is shaped by culture.

Man is a living system uniting the physical and spiritual, the natural and social, and hereditary and acquired traits. As a living organism, man is part of the natural chain of phenomena and is subject to biological (biophysical, biochemical, physiological) laws; at the level of conscious mind and personality, he is oriented toward society, with its specific laws. In terms of physical and morphological structure, man is the most highly organized matter in the known universe. He embodies everything that mankind has accumulated over the ages. This embodiment is achieved through exposure to cultural tradition and through biological heredity. A child inherits a store of genetic information by virtue of the specifically human structure of his body, brain, nervous system, and instincts. "*Man* is directly a *natural being*. As a natural being he is on the one hand endowed with *natural powers, vital powers*—inasmuch as he is an *active* natural being. These forces exist in him as tendencies and abilities—as *instincts*" (K. Marx, in K. Marx and F. Engels, *Iz rannikh proizvedenii*, 1956, p. 631).

However, natural (anatomical and physiological) instincts develop and are realized only under the conditions of social life, through a child's interaction with adults. Marxism repudiates metaphysical concepts about the existence of inborn ideas and capabilities in man. The way in which the biological principles of human life manifest themselves is socially conditioned. Man's life is

determined by a single system of conditions that includes both biological and social elements. The biological components of this unified system are simply the necessary conditions, not the driving force of development. Man's actions and his way of thinking and feeling depend on the objective historical conditions under which he lives and on the characteristics of the social group and class whose interests he represents, either consciously or unconsciously. His spiritual life and the principles by which he lives are not genetically programmed. This is definitely not the case, however, with respect to certain potential artistic aptitudes and individual gifts, which are shaped by society but are based on inherited traits. The development of man's propensities and capabilities is also affected to a certain degree by heredity, primarily through characteristics of the central nervous system.

A world of objects and social structures embodying the activity of preceding generations lies before every newborn human being. It is this humanized world, in which every object and process appears to be charged with a human significance, social function, and purpose, that surrounds man. Human cultural achievements, however, are not presented to man in a finished form but are rather implied in the objective circumstances in which they are embodied. The assimilation of social, historically shaped forms of activity is the fundamental condition and pivotal mechanism in the making of an individual. In order to transform these forms of activity into their personal abilities and make them part of their individual character, human beings from early childhood interact with adults, imitating and being taught by them. As a result, the developing individual acquires the ability to deal rationally with tools, various types of symbols, words, concepts, ideas, and the totality of social norms. As he assimilates the humanized natural world, the child becomes familiar with culture by various means. "Each of his *human* relations to the world—seeing, hearing, smelling, tasting, feeling, thinking, observing, experiencing, wanting, acting, loving—in short, all of the organs of his individual being" take part in this familiarization (*ibid.* p. 591).

During acculturation man develops mechanisms of self-control that are manifested as the ability to control by an effort of will a wide range of inclinations and instincts. This self-control, essentially social control, smothers impulses that are unacceptable to a given social group and constitutes a prerequisite for social life. The more intensively mankind develops, the more complex are the problems of education and upbringing, of the shaping of man as a personality.

Historically formed legal and moral norms, customs, rules of thought and grammar, and aesthetic tastes shape man's behavior and intellect, making individual people representatives of a particular way of life, culture, and psychology. Man "will develop his true nature only in society, and the power of his nature must be measured not by the power of the separate individual but by the power of society" (K. Marx and F. Engels, *ibid.*, vol. 2, p. 146). Marx criticized the concept of man as an isolated monad and emphasized that man remains in full contact with society even when he is alone. Man's awareness of himself always comes through his interaction with other people. Every man is a unique individual but at the same time he possesses a certain essence of the species. A man emerges as a personality when he attains self-awareness, an understanding of his social functions, and a consciousness of himself as the subject of a historical process. The formation of personality is bound up with social differentiation, with the separation of the individual from the collective through the expansion of personal rights and obligations.

The Marxist concept of man rests on the assumption that man can only be free in a free society, where he is not only the means by which social goals are achieved but is above all an end in himself. Marxism holds that the ideal society is a communist society, for only in such a society can man obtain the means that will enable him to realize fully his individuality.

Origin of man. Man's appearance on earth was the culmination of a complex and prolonged evolutionary development, and as a biological being, he retains close ties with the animal world. These ties are closest to the Primates, an order in which man makes up the hominid family. It is widely thought that the human evolutionary branch separated from the common anthropoid stem during the intense adaptive radiation of apes in the Miocene, most likely 12–15 million years ago. The most probable ancestor of man during this stage was *Ramapithecus* (or *Kenyapithecus*), a highly developed primate known from jaw fragments found in Asia (India, Pakistan), East Africa (Kenya), and Europe (Hungary).

The question of when the first hominids appeared is bound up with the hominization criterion itself, concerning which there are diverse opinions. If hominization is to mean a certain degree of assimilation by man's ancestors of a fundamentally new adaptive zone associated with the development of work activity and culture and with the appearance of a new mode of behavior, then from the morphological point of view the criterion must include the following: erect posture, initial adaptation of the wrist for performing work, and a fairly high level of development of the brain. Accordingly, the oldest authentic representative of the hominids was until recently considered to have been *Homo habilis* ("skillful man"), identified by the British scientists L. Leakey, P. Tobias, and J. Napier in 1964 on the basis of finds in the Olduvai Gorge. The advanced morphological features of *H. habilis* (erect posture and a high level of development of the brain, in which he surpasses all contemporary and fossil anthropoid apes) were linked to the earliest and most primitive stone implements known to science. This hominid, who lived approximately 2 million years ago, was probably the creator of the oldest Stone Age culture, the Olduvai culture.

Later discoveries, however, attested to the even greater antiquity of hominids, particularly the genus *Homo*. In the course of excavations in Kenya in 1972, R. Leakey found "skull 1470" and the accompanying skeletal remains of limbs in the area east of Lake Turkana, formerly Lake Rudolf. The absolute age of the find is more than 2 million years. The skull displays a number of advanced features, even when compared with later hominids, including a relatively high and rounded vault, slight projection of the frontal and occipital bones, and moderate postorbital constriction. The cranial capacity (770–775 cu cm) exceeds that of *H. habilis* (averaging 625 cu cm) and attains a size characteristic of some specimens of Archanthropinae. The shape of the femur is fully human. Working in Tanzania in 1975, M. Leakey found fragments of fossil hominids and stone implements in a stratum 3.5 million years old. Fossil hominids dating from approximately 3 million years ago had been discovered in Hadar (Ethiopia) in 1973–74. The chronological predecessors of modern man also include the Archanthropinae, who appeared some 1.9 million years ago (or perhaps earlier), and *Palaeoanthropus*, who lived from 300,000 to 35,000 years ago. The present species of man (*H. sapiens*) appeared no later than 40,000 years ago and possibly earlier. It would appear that Australia and the Americas were settled as early as the Upper Paleolithic. The predominant type of early *H. sapiens* was Cro-Magnon man, whose remains have been found both in Europe and elsewhere and who survived beyond the Paleolithic. Cro-Magnon man had a straight forehead, superciliary arches (instead of a supraorbital torus), a clearly formed chin protuberance, and a high cranial vault.

The general evolution of the hominids is quite complex and cannot be said to be fully understood. It is likely that during anthropogenesis branchings within polymorphic groups coincided with the direct development of individual branches and their "transformation by stages" (*see* PALAEOANTHROPUS and NEOANTHROPINAE). But these stages were widely coexistent, and their representatives may at times have shared the same culture.

E. N. KHRISANFOVA

Man's biological features. Man is classified as a member of the species *Homo sapiens* (thinking man), genus *Homo*, family Hominidae, order Primates, class Mammalia, and phylum Chordata. The human organism has many characteristics in common with

vertebrates, and especially with mammals. As in all vertebrates, the basis of man's internal skeleton is the spinal column, which is preceded during embryonic development by the notochord. Man has two pairs of extremities, a closed cardiovascular system, and a tubular nervous system. His body is structured on the principle of bilateral symmetry and exhibits metamerism, which is typical of all vertebrates.

As a mammal, man has a characteristic skin structure (a highly developed corium, or dermis, numerous sebaceous and sweat glands, and a covering of hair, albeit rudimentary over most of the body), a stable body temperature, pulmonary respiration, a four-chambered heart, erythrocytes without nuclei, and mammary glands producing milk for the nourishment of the young. Development of the embryo within the mother's body is accompanied in man, as in the other higher mammals, by the appearance of a special organ, the placenta.

Mammals have a well-developed nervous system and sensory organs, which helped them to survive and progress. Man advanced beyond the other mammals by virtue of the strong development and differentiation of his cerebral cortex.

Man's most characteristic anatomical and physiological features are his erect posture and gait, free upper extremities (for making and using tools), and highly developed means for social interaction. Also distinctive are certain features of the structure of the teeth, jaws, digestive glands, and alimentary organs. The need to maintain balance while walking erect has resulted in a curvature of the spinal column and a shift in the center of gravity.

The freeing of the upper extremities from their functions of body support and locomotion necessitated an increase in the size of the skeleton of the lower extremities, a powerful development of the muscles of the lower extremities, and the appearance of the arches of the feet, with their cushioning function. There was also a significant change in the structure of the pelvis, which became larger and wider and which came to serve as the main support for walking erect. All the internal organs adapted to erect posture; the means for supplying blood from the lower extremities to the heart and from the heart to the brain became more complex. The diaphragm shifted from a vertical to a horizontal position, and the muscles of the abdominal prelum acquired a significantly greater role in respiration.

Man interacts with other people by means of gestures, mimicry, and articulated speech, which are made possible by a corresponding development of the muscles, the vocal apparatus, and the means for controlling them, including the speech centers of the cortex. Articulated speech, the main channel of interpersonal communication, is inaccessible to animals.

Man's brain has surpassed the simian brain in both absolute and relative terms. A human brain weighs three times more than the brain of a gorilla, whose body weight is three times that of a man. Because of his remarkably well-organized nervous system, man has the prerequisites for unlimited intellectual and emotional progress.

Man is born with incompletely formed anatomical and physiological systems, but they are in the "human" mold. Thus, the parts of the skeleton and the muscles that are involved in walking erect are genetically preadapted even before a child's birth. The skeleton of children who develop using all four extremities for support (children reared by animals, mental defectives), as well as the skeleton of children with paralyzed lower limbs, remains human. In such animals as monkeys and dogs, enforced two-legged locomotion is capable of altering only certain structural features of the skeleton. Similarly, the morphophysiological characteristics of the vocal apparatus and the prerequisites for the subsequent development of speech are also established before birth. These features are absent even in animals that are closely related to man. Advanced development of the new areas of the cortex, and especially of those areas that will become the most highly differentiated, is observed during the ontogenetic development of the human brain. Consequently, man's social nature is manifested as soon as his hereditary information is implemented.

V. V. KUPRIIANOV

All modern men belong to a single species, which is subdivided into several main races. The main traits of the species *H. sapiens* are characteristic of all races of man, without exception. All races are thus at an equally high level of biological development, contrary to the reactionary assertions of racists. With respect to the time of origin and the number of centers of racial genesis, several hypotheses have been put forward. According to some of them, there was a single fairly extensive geographic area in which modern man, and the races of modern man, developed. Polycentric hypotheses postulate from two to four or five such centers. During the Paleolithic and Mesolithic the density of the population was extremely low, less than one person per 3 sq km. In the Neolithic the density increased approximately tenfold. By the year 1000 the population of the earth was 275 million, by 1500 it had expanded to 450 million, and by 1600 it had grown to 500 million. In 1800 the earth was inhabited by about 1 billion people, and in 1977 by approximately 4 billion.

The early stages in the development of hominids were probably closely associated with tropical forest-steppe and steppe regions. Subsequently, man significantly extended his habitat, settling even in deserts, polar areas, and mountain regions, although the largest modern groups inhabit tropical forests and temperate regions with mixed forests. Thus, *H. sapiens* is panecumenical, that is, a widely distributed species. He includes numerous populations that, upon interbreeding, produce fertile offspring and that exhibit significant phenotypical variability.

The intraspecies polymorphism of man's physique has been known since ancient times. Attempts to classify the various builds of the human body have resulted in the creation of constitutional schemes generally based on clearly delineated types. Since such schemes make it impossible to classify most people, increasing work has been done on the elaboration of quantitative methods that are based on a continuous distribution of constitutional components (muscles, bones, fat). Modern anthropology takes a comprehensive approach to the question of the human constitution, studying the correlation between morphological, physiological, biochemical, and psychological factors.

The quantitatively balanced polymorphism of man as a species reflects, to a certain extent, the adaptive radiation of human populations. Thus, for example, the proportion of the various types of physiques may vary significantly in different groups of mankind. A higher incidence of the "elongated type" is found among Arab desert dwellers, especially the bedouin of the Libyan Desert, or among the Nilotic peoples of Equatorial Africa. The "stocky build," on the other hand, is typical of certain variants of the arctic race (Eskimo). It is believed that such physiques are better adapted to maintaining physiological functions in a hot (or cold) climate through thermoregulation. As a general principle, the "ecological gradient" (the ratio of body weight to surface area) increases among inhabitants of colder climates and decreases among equatorial groups. Consequently, groups from colder climatogeographical zones are heavier and have a relatively smaller skin area.

The most clearly discernible forms of physiological adaptation are also observed under extreme living conditions, found primarily in northern, equatorial, and alpine regions. There is, for example, a decrease in the basal metabolic rate from northern to equatorial regions; the opposite tendency is observed for blood immunoglobulins, whose quantity increases in equatorial groups. Among mountain populations there is an increase in hemoglobin content. The origin of these traits is quite complex, although some of them are apparently genetically determined. For example, an effective method for stabilizing cholesterol has evolved among the East African Masai, whose food is generally very fatty but who nevertheless have low levels of cholesterol and virtually never suffer from atherosclerosis. Yet another example is the presumed decrease in tissue sensitivity to the metabolic effects of the growth (somatotropic) hormone among the nanitic Pygmies of Africa. The phenotype has also been found to depend on a whole range of external factors, the foremost of which are socioeconomic (nutrition, illness).

A specific feature of the interrelationship between man and his environment is the fundamentally new form of adaptation that he has created, in the course of which man alters his environment, causing simultaneous changes in human social relationships. This process takes place without a restructuring of man's morphofunctional organization. But man's biological adaptation is also of a specific kind for it involves the preservation of both his biological and social functions and is affected by the increasingly important

social factor. In contrast to animals, man preserves the morphofunctional characteristics of his species regardless of changes in his natural environment by means of sociohistorical labor activity. As a result of man's long-term influence on his surroundings a new, "artificial" environment has been created which, in turn, exerts a significant influence over various aspects of his vital activity. This process has gained momentum under the conditions of the scientific and technological revolution, in connection with further industrialization, urbanization, and the creation of artificial ecosystems. Since the middle of the 20th century the question of man's interrelationship with the environment has become a vital issue and has essentially been treated as the problem of man and the biosphere.

Sexual dimorphism and a uniform growth and biomorphosis are typical of all ethnoracial groups of *H. sapiens*. Sexual differences, manifested from the earliest stages of the postnatal period, are first expressed in the rate of development, inasmuch as indicators of biological growth show girls to be in the lead. Moreover, various harmful influences have a lesser effect on the growth processes of women than those of men, which is sometimes attributed to the "protective" action of the two X chromosomes in women. Sexual dimorphism is clearly manifested morphologically in overall bodily dimensions, proportions (relatively broader hips in women and wider shoulders in men), the development of "bodily components" (the better development of subcutaneous fat in women and of muscles and bones in men), microstructural features (muscle fiber diameter, dimensions and total number of fat cells), and certain histochemical characteristics. At all ages, there is a larger percentage of athletic types among men and of pyknic types among women. Studies also show that the athletic type in men and the pyknic type in women are characterized by relatively high levels of secretion of the sex hormones, androgens in males and estrogens in females. Finally, sexual differences also affect many physiological and biochemical traits. Thus, for example, body temperature, arterial pressure, pulse rate, red and white blood cell indexes, basal metabolism, and other factors exhibit a marked periodicity in women (in contrast to men) associated with the reproductive cycle.

A specific characteristic of man's individual development is his relatively long childhood with a comparatively slow rate of growth, followed by a leap in the growth rate in connection with sexual maturation. Chimpanzees and certain other apes exhibit a similar type of growth process, but with them the interval between rearing and sexual maturity is shorter. For this reason, these principles of growth may be viewed as being characteristic of a certain stage in the evolution of the primates, particularly of the hominids, in whose emergence the longer period of instruction of young individuals played an important role. This type of growth is characteristic of modern man, although there may be certain variations in the rates of development of groups and particularly of individuals.

Individual variations in the rate of development are apparent in any group of growing individuals, where there is always morphophysiological differentiation at a particular chronological age that determines, in the final analysis, the "biological age" of an individual. Criteria used to establish biological age include various morphological, physiological, and biochemical tests, including those showing the development of the skeleton (skeletal age) and dental system (dental age), sexual development, and hormonal status. Biological age is also determined on the basis of certain indexes of higher nervous activity that depend mainly on age, as well as indexes of the cardiovascular and muscular systems. All of these indexes can change either more or less synchronously or asynchronously, and they can reveal a tendency toward acceleration or retardation of development. The indexes of skeletal, sexual, and general somatic development, which are particularly closely interrelated, are most often used as criteria of biological age. The various indexes are of different diagnostic value, however, depending on age.

Rates of development, and consequently biological age, are influenced by many factors. Studies of twins have shown the importance of hereditary factors in determining the skeletal and dental ages, the quantity of sex hormones secreted, and the age at which menstruation begins. A very important role is also played by the socioeconomic factor; environmental factors (climatic, geochemical) have a lesser effect on biological age.

The "secular trend," which has been observed in many countries, especially during the last century, and which is manifested primarily as an acceleration of the developmental processes, an increase in physical dimensions, and some redistribution of physique types, is evidently just a variational phase within the limits of the *H. sapiens* species complex. Similar secular, or even epochal, changes may also have occurred much earlier. Indeed, anthropologists have determined that body length and the shape of the face and head have been changing since the Neolithic and even earlier. The dynamics of these phenomena has been thoroughly investigated by Soviet scientists. The processes of brachycephalization (an increase in the relative breadth of the head, expressed in cephalic indexes) and debrachycephalization (the opposite tendency) have been especially well studied. The Japanese researchers S. Morita and F. Otsuki (1973) point out, for example, that just over the past 50 years the cephalic index of Japanese men has increased by 3.3 as a result of a widening of the head. Studies by the Soviet anthropologist V. V. Bunak (1968) show that the average height of young Russian men increased by 3 cm in 40 years. Epochal variations have also been noted in indexes of sexual maturity, and they are possible for many other characteristics as well. All of these changes have been random, and the rate of change has varied with location and the period of human development.

The main reasons for these microevolutionary phenomena within the *H. sapiens* species are evidently of a genetic nature, associated chiefly with the interbreeding of the planet's populations, changes in gene frequencies, and alterations in dominance, although the manifestation of such phenomena also depends on a series of other factors, including socioeconomic ones. Nevertheless, the freeing of Neoanthropinae from the species-forming type of natural selection, the stabilizing form that natural selection takes in modern society, and the development of panmixia, which conteracts the natural mutational process, make it impossible to predict at this time any important changes in the *H. sapiens* species complex that emerged in the Upper Paleolithic.

MANDIBULAR ARCH, a supporting element of the visceral skeleton in gnathostomatous vertebrates, including humans. The mandibular arch is situated directly in front of the sublingual arch. In the course of evolution, the mandibular arch differentiated into the primary upper jaw (palatoquadrate cartilage) and primary lower jaw (Meckel's cartilage). [29–156–1]

MANGE, a disease in animals caused by various itch mites parasitic to the animals. Various types of mange are distinguished according to the mite species and its location on the skin, for example, acaridic mange, psoroptic mange, feather mange, chorioptic mange, and otodectic, or ear, mange. Itch mites are host specific species. For example, among the psoroptic mites, *Psoroptes equi* parasitizes horses, *P. bovis* parasitizes cattle, and *P. ovis* parasitizes sheep.

For symptoms, treatment, and prevention of mange diseases, *see* ACARIASIS; DEMODETIC MANGE; and CHORIOPTIC MANGE.

[29–342–2]

MARASMIUS SCORODONIUS, a capped basidiomycetous fungus of the family Tricholomataceae. The cap, which measures 1–3 cm across, is reddish, yellowish, or brownish. Initially bell-shaped, the mushroom eventually becomes flattened. The stalk, which reaches 4 cm in height and 0.5–2 mm in diameter, is red-brown below and lighter above. *M. scorodonius* grows from July to September in the edges and glades of coniferous and hardwood forests on fallen leaves (needles) and branches, especially after a rain. *M. scorodonius* has the odor and taste of garlic; it is used as a seasoning. The mushroom dries well and retains its odor. [29–342–1]

MARRUBIUM (horehound), a genus of plants of the family Labiatae. The plants are perennial or, less commonly, annual woolly herbs with opposite entire leaves. The pink, violet, white, or yellow flowers are gathered into dense false whorls in the axils of the uppermost leaves. The corolla has a flat upper lip. The fruit consists of four nutlets.

There are about 40 species, distributed in North Africa and the temperate and subtropical belts of Eurasia. The USSR has 15 species, growing mainly on dry slopes in the Caucasus. The most common species is the white-flowered common horehound (*M. vulgare*), which occurs in the western and southern regions of the European portion, in the Caucasus, and in Middle Asia. The plant usually grows near roads, in crops, on long-fallow land, and in wastelands. The common horehound contains a substantial amount of nectar. Many species contain tannin. [29–832–4]

MATRIX BALANCE SHEET (Russian, *shakhmatnaia oborotnaia vedomost'*), a form used to show bookkeeping entries in a profile of corresponding synthetic accounts and to provide periodic summaries. It lists totals for economic operations of a similar nature. A matrix balance sheet consists of a table in which debits are entered in horizontal rows and credits are entered in vertical columns. All operations pertaining to the given corresponding accounts have their totals (turnovers) entered at the points where the columns and rows intersect. A single entry thus gives two indications of an operation.

Unlike a simple consolidated balance sheet, a matrix balance sheet not only gives totals for the turnovers of each account but also lists the components of the turnovers. This makes it possible to verify the completeness and accuracy of entries in the various accounts, to ascertain the primary economic factors of operations as reflected in the debit and credit side of each account, and to detect errors in the correspondence of accounts. A matrix balance sheet occasionally includes inventories for synthetic accounts in addition to turnovers; in such instances the term *shakhmatnyi balans* is sometimes used in Russian.

Although a matrix balance sheet is too unwieldy and complex to be used in all forms of accounting, the matrix principle is widely used to create accounting registers. Thus, in the summary-journal form of accounting, all basic registers are constructed in matrix form, thereby substantially reducing the volume of accounting operations. [29–894–1]

MATTE, an intermediate product or a by-product in nonferrous metallurgy. A matte is an alloy of variable chemical composition that consists of iron sulfide and sulfides of nonferrous metals.

Owing to the low solubility of sulfides of nonferrous metals in oxide melts, the relatively low melting point (below 1100°C) of such sulfides, and the high density (greater than 4 g/cm^3) of the sulfides, a molten matte separates from a slag upon smelting and forms a separate layer below the slag. A matte is a primary product into which copper, nickel, and cobalt go when a copper sulfide or nickel sulfide raw material is smelted or when oxide ores are processed by means of certain techniques. Mattes usually contain 10–50 percent Cu and Ni, 15–25 percent S, and Fe as the remainder. Mattes are also produced in lead smelting when copper and sulfur are present in the raw material. As a rule, noble metals and metal impurities in raw materials accumulate in mattes.

Mattes are processed in a converter (*see* CONVERTER BLOWING OF MATTE), where the sulfur is oxidized and the iron is converted from the sulfide form to the oxide form and, together with silica, yields converter slag. The copper sulfide and nickel sulfide are subjected to further processing after the iron is removed.

Nickel matte produced in smelting is sometimes called raw matte. A matte that is produced after converter blowing and has an iron content of less than 3 percent is referred to as converter matte. A matte with an intermediate iron content is known as furnace matte. Copper matte that is produced after the completion of the first blowing period and contains < 1 percent Fe is called white matte. I. D. REZNIK [29–1463–2]

MAY FOURTH MOVEMENT, a mass anti-imperialist movement in China in May and June 1919.

Influenced by the Great October Socialist Revolution in Russia, the May Fourth Movement developed in response to the decision of the Paris Peace Conference not to return to China the former German concessions in Shantung, which had been captured by the Japanese. It began on May 4, 1919, in Peking, where students demonstrated against the decision and the betrayal of Chinese national interests by the venal leaders of the Peking government. The police arrested several dozen demonstrators; the students of Peking responded the following day by boycotting classes and declaring a strike.

The action of the students in Peking was supported by students in other cities, and in early June workers, the urban petite bourgeoisie, and the nationalist bourgeoisie joined the struggle. The principal center of the movement shifted from Peking to Shanghai, where 50,000–70,000 workers and nearly all the merchants went on strike. Under pressure from the popular masses, the Peking government was forced to dismiss the three officials who had compromised themselves most by their ties with the Japanese imperialists. The May Fourth Movement provided a strong impetus to the development of the working-class and national liberation movement in China and fostered the dissemination of Marxism throughout the country.

V. P. ILIUSHECHKIN [29–351–3]

MELITAEA AND EUPHYDRYAS, two closely related genera of butterflies of the family Nymphalidae. The wingspread is 2–5 cm. The wings are brown above, with transverse parallel stripes of many black spots. The underwings are usually light yellow with an intricate black pattern. The caterpillars, which have spines distributed in rows along the body, feed on the leaves of herbaceous plants, trees, and shrubs. They spend the autumn and winter in groups in weblike nests. Those that have wintered live singly.

Melitaea and *Euphydryas* are distributed in Europe, nontropical Asia, and northern Africa. Of the approximately 150 species, about 50 occur in the USSR. Among the most common species is *M. maturna*, which flies from May to July and whose caterpillars live on leafy trees and shrubs (poplars, willows, lilacs, honeysuckle) and herbaceous plants (plantain, wood sorrel, violets, scabious). The butterfly is distributed in the central and steppe belts of the European USSR, in southern Siberia, and in the Far East. Also common are *M. cinxia* and *M. athalia*, which are distributed in the European USSR, in the Caucasus, in Siberia, and in the Far East. Their caterpillars feed on herbaceous plants (plantain, hawkweed, cowwheat). [29–920–1]

MEROPIDAE, a family of birds of the order Coraciiformes. The body measures 15–35 cm in length. The bill is compressed and slightly curved. The wings are long and pointed, and the flight is rapid. The legs are short and the birds walk clumsily. The plumage is dense, shiny, and alike in both sexes. Dark blue, green, and yellow tones predominate.

The family comprises seven genera, which include 21 species. The Meropidae are distributed in the temperate and tropical parts of Europe, Africa, Asia, and Australia. Some species are migratory. There are two species in the USSR: the common bee-eater (*Merops apiaster*), which is found in the south, from Moldavia in the west to as far east as the Altai and as far north as Kazan and Ufa, and the blue-cheeked bee-eater (*Meropidae superciliosus*), which lives in the arid parts of the Caspian Region and Middle Asia. Both species are migratory.

The Meropidae inhabit open spaces, shunning forests. They nest in colonies in burrows dug in cliffs or flat areas. The clutch contains two to nine white eggs, which are incubated by both the male and female. The young are bare upon hatching. The diet consists of insects, including wasps and bees, which, like the swallows, the Meropidae catch on the wing, taking off from a branch or edge of a cliff. The Meropidae are harmful to apiculture, since they feed on bees. [29–1620–5]

MINE, UNDERGROUND (in Russian, *shakhta*), a mining enterprise that extracts minerals by underground methods and ships them to a consumer or an ore-enrichment plant. An underground mine includes both surface structures—for example, headframes, headhouses, and storehouses—and all the underground mining excavations that are used to work a deposit within a mine area. Such a mine is a mechanized and automated enterprise equipped with efficient machinery and devices for the extraction and hauling of minerals, for the sinking of mining excavations, for the removal of mine water, and for ventilation. Underground mines that work large deposits have lives of 50–70 or more years.

The largest underground coal mine in the USSR is the Raspadskaia Mine, which is in the Kuznetsk Coal Basin and has a projected eventual output of more than 7 million tons a year. The largest underground iron mine in the USSR is the Gigant Mine, which is in Krivoi Rog and has a projected eventual output of 12 million tons a year. The deepest underground mine in the USSR is the Academician A. A. Skochinskii Mine, which is in the Donets Coal Basin and is 1.2 km deep.

The deepest underground mines in the world are gold, silver, and diamond mines; they are 4–4.5 km deep. They include the Champion Reef gold mines in India and the Witwatersrand gold mines in the Republic of South Africa. [29–907–1]

MINE AREA, a mineral deposit or the portion of a deposit that is assigned for working by a single mine. A mine area is delineated according to the strike, rise, and dip of the seam or stratum; that is, the area is bounded on the sides, from above, and from below.

When a deposit is divided into mine areas, the boundaries of the areas are fixed during the planning stage either on the basis of technological and economic considerations or in accordance with major geological disturbances and barrier pillars. If a deposit's strata are undisturbed, the mine area is shaped as a rectangle with the long side following the strike.

A mine area contains mineral reserves whose extent predetermines the production capacity and life of the mine. [29–912–2]

MINE HOIST, a set of machines and devices that are used to raise or lower personnel and loads in vertical or inclined shafts.

A mine hoist (Figure 1) includes a hoisting machine, hoist cables, receptacles, and sheaves; the sheaves are mounted on the headframe. Useful minerals are loaded into the receptacles by means of a loading chute and are discharged into a bin. The hoisting machine (Figure 2) comprises a winding drum or driving sheave, a brake, reduction gears, an electric motor, and a control console.

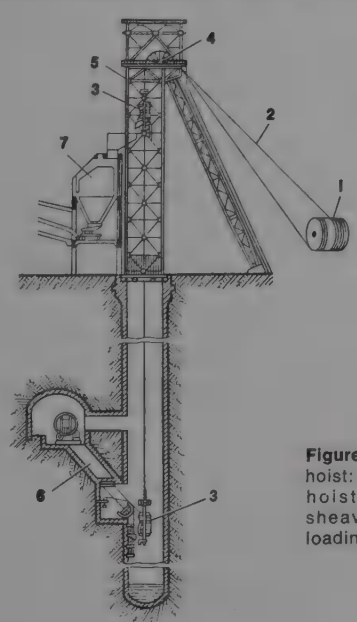

Figure 1. Diagram of a mine hoist: (1) hoisting machine, (2) hoist cables, (3) skips, (4) sheaves, (5) headframe, (6) loading chute, (7) bin

Depending on their purpose, various types of mine hoists are distinguished. Main hoists are used to raise useful minerals and barren rock to the surface. Auxiliary hoists are employed to raise or lower personnel and various loads. Sinking hoists are used in the sinking or deepening of shafts. Inspection or emergency hoists are employed to inspect shafts or to raise personnel in emergencies.

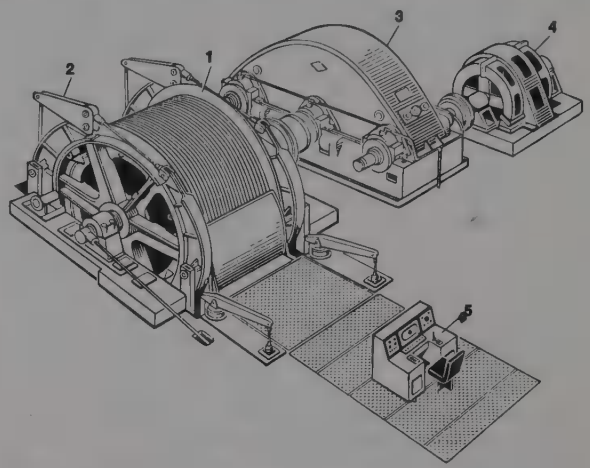

Figure 2. A hoisting machine with a cylindrical drum: (1) winding drum, (2) brake, (3) reduction gears, (4) electric motor, (5) control console

The receptacles used in mine hoists may be cages, skips, or buckets. Depending on whether or how the weight of the hoist cables is balanced, the hoisting may be unbalanced, statically balanced, or dynamically balanced. The winding drum or driving sheave may have a single radius or a large and a small radius. Cylindrical drums and Koepe sheaves have a single radius; bicylindroconical drums have a large and a small radius.

Electric motors with an output of up to 5,000 or more kilowatts (kW) are used in hoisting machines. AC induction motors are widely employed. The output of such motors is 1,800–2,000 kW for skip hoists or 800–1,000 kW for hoists that raise and lower cages. DC motors are usually employed in high-capacity hoists.

From the viewpoint of engineering and economy, the best maximum cable speeds range up to 20 m/sec for hoisting loads and up to 12 m/sec for hoisting personnel.

Multirope friction winders are promising. Such hoisting machines are tower mounted over shafts and are used to hoist two skips or two cages or to hoist a single receptacle balanced by a counterweight. In particular, hoists driven by multirope friction winders are used to service several levels at the same time.

MINE PROBE, a pointed, steel-tipped rod that is 2–3 m long and is used for detecting antipersonnel and antitank mines buried at a shallow depth. In searching for mines, the probe is thrust into the ground every 20 cm at an angle of 20°–45° and to a depth of up to 15 cm. If the probe strikes a hard object beneath the surface, the spot is examined thoroughly. [29–1619–2]

MINE TELEPHONE, a mine rescue wired-communications device that provides direct two-way communication with loudspeakers between an underground base and a mine rescue squad.

The Sh-1 mine telephone, which is used in the USSR, consists of a base set and two squad sets. The squad sets may be held in the hand or fastened to the work outfit with a spring hook. Semiconductor devices and printed wiring are used in the electrical components of the telephone sets, which are designed to operate with general-purpose cable drums.

The Sh-1 mine telephone is designed for continuous operation at temperatures of 0° to 50°C, at relative humidities of up to 90 percent, and under conditions of exposure to coal dust, foul air, and underground water. The telephone has a communications range of 5 km and operates continuously for 100 hr without replacement of the power source. It is sparkless and, together with its carrying case, weighs 4.8 kg. [29–916–1]

MONTENEGRINS, a nation in Yugoslavia, numbering 508,800 persons (1971 census), most of whom live in Montenegro (355,600) and Serbia (125,300). Montenegrins speak the Štokavian dialect of Serbo-Croatian. The majority of believers belong to the Orthodox Church, and the rest are predominantly Muslims.

In terms of culture and way of life, the Montenegrins have much in common with the Serbs. However, the geographic isolation of their mountainous homeland, the centuries of struggle for independence from the Ottoman Empire, and the resultant militarization of life hindered Montenegro's socioeconomic development and helped preserve the patriarchal clan social order. Although the ethnic composition of the Montenegrin clans (Vasojevići, Piperi, Kući, Belopavlići) was somewhat mixed owing to the influx of refugees from other parts of the country and groups of Albanian origin, it was popularly believed that all the members of a clan had a common ancestor and were blood relatives. Livestock raising and farming were the traditional occupations.

After the proclamation of a socialist Yugoslavia in 1945 and the creation of the republic of Montenegro, mechanization and new techniques were introduced in agriculture, and industrial enterprises were established. The former cultural backwardness of Montenegro has been overcome. The indigenous applied arts, notably wood and stone carving, metalworking, and embroidery, are flourishing. Oral poetry, music, and dance continue to develop vigorously. (For more information about the history, economy, and culture of the Montenegrins see MONTENEGRO.)

M. S. KASHUBA [29–276–1]

MONTENEGRO (Crna Gora), Socialist Republic of Montenegro (Socijalistička Republika Crna Gora), a republic in Yugoslavia. Situated in the southeastern part of the Dinaric Alps and washed by the Adriatic Sea, Montenegro covers an area of 13,800 sq km and has a population of 575,000 (1977). Montenegrins, who speak Serbo-Croatian, constitute more than two-thirds of the population, which also includes Bosnians, Serbs, and Albanians. The capital is Titograd.

A socialist republic, Montenegro has voluntarily joined with other, equal socialist republics to form a federated state, the Socialist Federal Republic of Yugoslavia. Its present constitution was adopted in 1974. The supreme governing body is the republic Skupština (assembly), which consists of three chambers—the Council of Associated Labor, the Sociopolitical Council, and the Council of Communes. The government (cabinet) of the republic is the Executive Council.

Natural features. A large part of Montenegro is occupied by the Dinaric Alps, which rise to 2,522 m on Mount Durmitor. The Montenegrin Karst Plateau lies in the southwest. The marginal ridges of the highland descend precipitously toward the Adriatic, leaving only a narrow strip of coast. The northern shore of Lake Scutari is fringed by a lacustrine plain. The prevailing temperate continental climate gives way to a Mediterranean climate along the coast. The precipitation ranges from 1,600 mm to 1,800 mm annually, increasing to 3,000 mm near the coast. The mountain slopes are covered with coniferous and mixed forests. Mediterranean shrub vegetation grows along the Adriatic coast.

Historical survey. Inhabited from Paleolithic times, Montenegro was settled in the Bronze and Iron ages by Illyrians, who were conquered by the Romans in the first century B.C. In the next century the territory became part of the Roman province of Dalmatia, and in 297 it was included in the province of Praevalitana. (Called Dioclea until the 11th century, when it was renamed Zeta, the land acquired its present name in the 15th century.) In 493 some of the area was absorbed into the Ostrogothic state, and in 536 it fell under Byzantine control. In the seventh century Montenegro was settled by Slavs, who were converted to Christianity in the ninth century.

During the reign of Prince Vladimir (c. 970–1016) the area came under the rule of the Bulgarian king Samuil, but in 1018 Byzantium reasserted its hegemony. Under Prince Vojislav (1031–51), Montenegro freed itself from Byzantine control and annexed Travunija and Zahumlje. In 1077, Prince Mihailo assumed the royal title. During the reign of King Bodin (c. 1082 to c. 1101), all of Serbia was incorporated into Zeta. Feudal relations developed in the country, and the coastal cities of Kotor, Budva, Bar, and Ulcinj prospered. Montenegro was absorbed into the Serbian Nemanja state under Stefan Nemanja (ruled c. 1170–96), regaining its independence only in 1366 after the death of Stefan Dušan.

The succeeding native rulers—the Balšić princes (1361–1421) and the Crnojević princes (1422–1528)—were compelled to fight against Venice and the Ottoman Empire. Between 1396 and 1443 Venice gained control over the Montenegrin coastal cities, and in 1479 Turkish forces seized Scutari and established themselves in the plains region. In 1499, Montenegro was officially included in the Ottoman Empire, but the Montenegrins stubbornly refused to recognize the authority of the conquerors. Feudalism had made little headway in the country, where much of the land was controlled by extended families called *zadrugas*. The *zadrugas* banded together to form clans, which in turn formed tribes ruled by elders called *knezes* and *vojvodas*.

In an effort to assert their independence, the Montenegrins sided with Venice in the Venetian-Turkish War of 1645–69 and in the Holy Alliance's war against the Ottoman Empire (1683–99). Bishop Danilo Petrović-Njegoš (ruled 1697–1735), who founded the Njegoš dynasty, killed or expelled the pro-Turkish feudal lords, that is, Montenegrin noblemen who had converted to Islam. Under Danilo a judicial body was created for all of Montenegro, called the Court of Bishop Danilo, and the country established closer ties with Russia. In 1711 the Montenegrins responded to Tsar Peter I's call to join the war against the Ottoman Empire. By the Treaty of Passarowitz (Požarevac, 1718), which concluded the war between the Ottoman Empire on the one hand and Austria and Venice on the other, Venice received a number of coastal communities, depriving Montenegro of access to the sea.

During the reign of Petar I Petrović-Njegoš (1781–1830), Montenegro's ties with Russia were greatly strengthened. After the Austro-Russo-Turkish War of 1787–91, the Montenegrins began their drive for independence by defeating the army of the Scutari vizier Mahmud Pasha Bušatli at the battle of Kruse on Sept. 22, 1796. During the Napoleonic wars and the rise of the national liberation struggle of the Serbian people (1804–15), the Montenegrins sided with Russia and Serbia. In 1813 they gained control of Boka Kotorska, which was returned to Austria at the Congress of Vienna (1814–15). Petar II Petrović Njegoš (ruled 1830–51) strengthened the central government and established the Administrative Senate (1831). Petar's successor, Danilo (ruled 1851–60), proclaimed Montenegro a hereditary principality in 1852.

During the Bosnia-Hercegovina uprising of 1875–78, Montenegro gave the rebels military and material aid, and in 1876 it joined Serbia in declaring war on the Ottoman Empire. Achieved as a result of the Russo-Turkish War of 1877–78, Montenegro's independence was confirmed by the Berlin Congress of 1878, which recognized Montenegro's jurisdiction over the areas of Podgorica, Kolašin, Nikšić, Žabljak, Bar, and Ulcinj but significantly reduced the territory awarded to Montenegro earlier that year by the Treaty of San Stefano.

Capitalist development, which began in the first half of the

19th century, gained momentum in the last third of the century. Several changes took place in the superstructure: in 1879 the Senate was replaced by the State Council, ministries, and the High Court, and in 1888 the Property Code was adopted, introducing some norms of bourgeois law. The first labor organization, the Workers' Alliance, was formed in 1903. Under the influence of the Russian Revolution of 1905–07, opposition to the autocratic regime of Prince Nikola (ruled 1860–1918) mounted, leading to the formation of the People's Party in 1906. The constitution of 1905 established the Skupština (assembly) as a permanent body. Proclaimed a monarchy in 1910, Montenegro joined the Balkan League in 1912 and took part in the Balkan Wars of 1912–13. As an ally of the Entente in World War I, Montenegro was occupied by Austro-Hungarian forces from January 1916 until the autumn of 1918. Looking to Russia and France for support, the majority of bourgeois émigrés formed in March 1917 the Montenegrin Committee of National Unification, which in August accepted the Corfu Declaration.

Under the impact of the October Revolution of 1917 in Russia, Montenegrins launched a mass movement for national and social liberation and for unification with Serbia on a democratic basis. Meeting in Podgorica in November 1918, the Great People's Skupština adopted a resolution calling for union under the aegis of the Serbian king. On Dec. 1, 1918, Serbia, Montenegro, and the Yugoslav (South Slav) areas of former Austria-Hungary united to form the Kingdom of the Serbs, Croats, and Slovenes, renamed Yugoslavia in 1929. In the new state Montenegro was a backward agrarian hinterland. Bent on creating a Greater Serbia, the ruling elite hindered the economic growth of Montenegro and tried to impose Serbian customs on the inhabitants. After the coup of 1929 and the establishment of a military-monarchist dictatorship in Yugoslavia, Montenegro ceased to exist as an independent administrative unit.

In April 1941, Montenegro was overrun by fascist troops along with the rest of Yugoslavia. The Italian occupying forces designated the area a governorate. During the National Liberation War in Yugoslavia (1941–45), led by the Communist Party of Yugoslavia (founded 1919), Montenegro became one of the centers of armed resistance. The July 13, 1941, uprising against the occupying forces is now celebrated as the Day of the Uprising of the Montenegrin People. A national democratic governing body, the National Liberation Committee, was formed on July 21, 1941. The Regional Antifascist National Liberation Council of Montenegro and Boka, formed in November 1943 in Kolašin, was reorganized as the Antifascist National Liberation Skupština of Montenegro in July 1944. Montenegro was completely liberated from the fascist occupying forces and their accomplices by the National Liberation Army of Yugoslavia on Dec. 31, 1944. The People's Government of Montenegro and a supreme legislative and executive body, the People's Skupština of Montenegro, were established in April 1945.

When the Federal People's Republic of Yugoslavia (FPRY) was proclaimed on Nov. 29, 1945, Montenegro became one of its six national constituent republics. The status and sovereign rights of the People's Republic of Montenegro (PRM) as an equal member of the federation were guaranteed by the constitution of the FPRY, adopted in January 1946, and by the constitution of the PRM, promulgated in December 1946. Like the rest of Yugoslavia, Montenegro underwent profound socioeconomic transformations that enabled it to embark on socialist construction. The achievements in socialist construction, based on self-government, have been recorded in two successive constitutions of the Socialist Federal Republic of Yugoslavia and the Socialist Republic of Montenegro, promulgated in 1963 and 1974. The leading ideological and political force of the SRM is the League of Communists of Montenegro, an integral part of the League of Communists of Yugoslavia. The Socialist Alliance of the Working People of Montenegro belongs to the Socialist Alliance of the Working People of Yugoslavia.

A. E. MOSKALENKO (through the 18th century) and I. G. IANU

Economy. With 2.6 percent of Yugoslavia's population, Montenegro in 1975 accounted for 1.8 percent of the national income, 1.5 percent of the country's gross industrial output, and 1.5 percent of its agricultural output. According to the 1971 census, 21.3 percent of the economically active population was engaged in industry and construction, compared to about 3 percent in 1939, and 43.3 percent was employed in agriculture, forestry, and fishing, as against more than 80 percent in 1939. Industry provides more than half and agriculture one-sixth of the national income. The industrial output increased by a factor of 14 from 1945 to 1974.

Most of the industries are engaged in the extraction and refining of mineral raw materials and the processing of agricultural products. The bauxite mines near Nikšić yield approximately one-fifth of Yugoslavia's output. Lead and zinc ore is extracted near Pljevlja and Ivangrad, and lignite and salt (along the coast) are also mined. Hydroelectric power plants have been built on the Zeta River. Other industrial facilities include a metallurgy combine in Nikšić (steel, rolled metal), an aluminum combine in Titograd, wood-products combines in Mojkovac, Ivangrad, and Titograd, electrical engineering plants in Cetinje, shipyards in Kotor, and textile, food, and tobacco enterprises in Titograd, Kotor, and Bar.

The chief branch of agriculture is pasture livestock raising, chiefly sheep and low-yield cattle. The republic's more than 500,000 sheep account for about 6 percent of the country's total number. Mountain pastures and meadows cover 40 percent of Montenegro's area and arable land, 6 percent. Corn, wheat, barley, and potatoes are grown in the Scutari Basin, the river valleys, and the intermontane basins. The republic produces large quantities of plums, figs, pomegranates, and almonds, about four-fifths of the country's oranges, some two-thirds of its tangerines, and half of its lemons. There are also olive groves and vineyards.

Montenegro's largest seaports are Bar and Kotor. The main railroad runs from Belgrade to Bar (opened in 1976), and there is a good network of highways. The principal airport is in Titograd. The republic has seaside health resorts and other tourist attractions.

S. N. RAKOVSKII

Cultural affairs and public health. In 1975, 97 percent of the Montenegrin population was literate. In the 1974–75 school year the republic's 643 basic eight-year schools had a combined enrollment of about 91,500 pupils. That year more than 9,400 students were enrolled in the republic's 16 *Gymnasiums*, which offer a complete secondary education. Vocational schools, technical schools, and other special schools were training more than 15,700 students, and some 5,500 students were attending the republic's five higher educational institutions. A university was founded in Titograd in 1973.

The majority of research institutions are located in Titograd. They include the republic's highest scientific institution, the Montenegro Academy of Sciences and Arts (founded 1976), the History Institute, the Institute of Geological and Chemical Research, the Institute of Hydrometeorology, and the Seismological Station. In Kotor there is an institute of marine biology.

In 1975, Montenegro had 11 research and specialized libraries, 19 public and 476 school libraries, one museum, four drama theaters (one professional, one amateur, and two children's theaters), and 30 motion-picture theaters. A radio station and a television studio operate in Titograd. In 1975 the republic issued 46 newspapers with a total circulation of 5,077,000, 15 magazines with a total circulation of 229,000, and 140 book and pamphlet titles with a total printing of 552,000 copies.

In 1974 health care was provided by eight hospitals, 94 outpatient clinics, 52 dental offices, 13 tuberculosis dispensaries, 24 gynecological clinics, 20 polyclinics for preschool children, and 14 polyclinics for schoolchildren. There were 31 pharmacies. Montenegro's best-known seaside health resorts are Herceg Novi and Bar.

Literature. The development of Montenegrin literature has not been adequately elucidated in Yugoslav literary scholarship. Whereas some literary scholars regard Montenegrin literature as an integral part of Serbian literature, others insist that it developed along separate lines. In general, Montenegrin literature developed through close interaction with other Yugoslav, particularly Serbian, literature, a circumstance fostered by ethnic and linguistic kinship, common historical and cultural traditions, and the ties between Montenegrin and Serbian cultural and literary figures. However, the extent of literary interaction has not been uniform at different stages of the literary process: the striving for

autonomy was more marked in the second half of the 19th century, and the tendency toward fusion with Serbian literature was more pronounced in the first half of the 19th century and the period between the two world wars. In socialist Yugoslavia the further consolidation of the national literary forces has been accompanied by a strengthening of the multifaceted contacts with other Yugoslav literatures.

Montenegro's rich folklore tradition originated in the distant past. Religious works, saints' lives, and prayer books have survived from the Middle Ages. The most important works of the 17th and 18th centuries are the manuscripts of A. Zmajević (1624–94) and I. A. Nenadić (1709–84), the *History of Montenegro* (1754) by V. Petrović (1709–66), and the *Epistles* of Petar I Petrović-Njegoš (1747–1830).

Most scholars date the beginning of modern Montenegrin literature from the end of the 18th and first half of the 19th centuries. Its founder was the poet and statesman Petar II Petrović-Njegoš (1813–51), whose works continued the heroic tradition of the folk epic. Njegoš evoked a poetic picture of Montenegrin life and extolled the struggle of the Montenegrins and Serbs for liberation from Ottoman oppression. His finest work, the dramatic epic *Mountain Garland* (1847), is animated by the idea of the unification of the South Slavs. Njegoš also played a prominent role in the development of early romanticism in Serbian literature.

Romantic poetry flourished from the second half of the 19th century until World War I. Its leading exponents were S. Perović-Cuca (1830–57), Nikola I Petrović (1841–1921), and M. Šobajić (1836–1917). Prose was largely limited to ethnographic fiction, such as the *Stories of Montenegro and the Coast* (1875) by S. Mitrov Ljubiša (1824–78), and memoirs, of which the best known were those of M. Miljanov (1833–1901). Two noteworthy historical plays were written: *Balkan Empress* by Nikola I Petrović (1884) and *Emperor's Way* (1894) by R. Roganović Crnogorac (1859–1900). The literature of the period, essentially folkloric and romantic, celebrated the patriarchal way of life, the historical past, and heroism.

Despite the national conflicts that existed in the military-monarchist dictatorship that was established in Yugoslavia in January 1929, the number of Montenegrin writers grew steadily. The genre and thematic framework of literature expanded, and prose underwent intensive development. In the early 1930's, Montenegrin literature, like the other Yugoslav literatures, came under the influence of "social realism," a literary movement that championed realism and drew inspiration from revolutionary ideology. Social realist poetry reached a high level in the collections *Kulak* (1936) and *Fiery Doves* (1937) and the narrative poem *Newcomers* (1937) by R. Zogović (born 1907), the collections *Forests* (1938) and *Fiery Mornings* (1941) by M. Banjević (1905–68), the collection *Two Rivers* (1938) by J. Djonović (born 1909), and the narrative poem *Through Blue Twilight* (1929) and the collection *Land* (1934) by M. Vuković (1910–46).

The social and psychological palette of prose also became richer, and the first novels appeared. The life of the Montenegrin people was realistically portrayed by R. Ratković (1903–54), noted for his novel *Nevidbog* (1933), D. Djurović (born 1901), whose short-story collection *Among the Mountain People* (1936) and novel *The Land of Duklja* (1939) were widely acclaimed, and N. Lopičić (1909–45), best known for his short-story collection *Peasants* (1939). Many Montenegrin writers took part in the War of National Liberation in Yugoslavia.

After Montenegro's liberation from the fascist occupying forces and their collaborators on Dec. 31, 1944, and the establishment of a people's government the next year (a socialist republic was created in 1963), literature entered a remarkably fruitful period of development. The intensive growth and further consolidation of Montenegro's literary forces was reflected in the founding of the literary magazines *Creation* (1946) and *National Culture* (1951) and in the formation of the Society of Montenegrin Writers (1956).

The main literary figure since the 1950's, M. Lalić (born 1914) has vividly depicted the national liberation struggle and revolution in his novels *The Wedding* (1950), *Vicious Spring* (1953), *The Rupture* (1955), *The Round-up* (1960), and *Leleja Mountain* (1962). The national problems of the late 19th and early 20th centuries are treated in Lalić's historical novel *Military Luck* (1973). Other outstanding prose works of this period include the short-story collections *Long Moments* (1956) and *Playing With Fire* (1966) by S. Asanović (born 1931), the novels *Fast and Deep* (1959) and *Watershed* (1968) by Č. Vuković (born 1920), and the short-story collection *Facing the Truth* (1961) and the novella *Mouthful of Dirt* (1974) by Branimir Šćepanović (born 1937). These works deal with the national liberation war and contemporary life, focusing on moral, ethical, and psychological problems.

Among the finest public achievements of the postwar period are Zogović's collections *Stubborn Stanzas* (1947), *Articulated Word* (1965), and *Personal, Purely Personal* (1971), Djonović's collections *Mountain Streams* (1947) and *Yearning for the Road* (1961), and Banjević's narrative poem *Sutjeska* (1946) and his collection *Till It Sparks* (1961). Other important verse collections include *Poems* (1947), *Nets* (1955), and *Forgotten Snows* (1958) by D. Kostić (born 1917) and *Whirlpool* (1950) and *Ribbons in the Valley* (1955) by R. Vešović (born 1921). A quest for new themes and forms distinguishes the poems of M. Kralj (born 1933), S. Perović (born 1932), Blažo Šćepanović (1934–66), and J. Brković (born 1933). The leading contemporary playwrights are Brković, V. Ivanović, Ž. Komanin (born 1935), and B. Radović. Literary criticism is represented by B. Milačić (born 1920), M. Stojović (born 1927), and R. Rotković (born 1931).

Architecture and art. The Neolithic pottery discovered at Crvena Stijena, with its simple modeled ornamentation or painted geometric designs, closely resembles the Neolithic ware found in Serbia and Rumania. Archaeological investigations have uncovered Illryian fortified settlements and necropolises dating from the late Bronze Age and early Iron Age. In the period of Greek and Roman conquests, Montenegro fell within the orbit of classical culture, whose traditions survived in a simplified form during the Byzantine period (sixth century A.D.) and after the coming of the Slavs in the seventh century. There are remains of Roman fortifications, dwellings, basilicas, and architectural fragments with fine carving at Duklja (Dioclea), near Titograd.

In medieval Montenegro, Italian and Dalmatian cultural influences coalesced with those of Serbia and Byzantium. In the ninth and tenth centuries modest single-aisled cruciform or three-apse churches were constructed of cut or broken stone. The Romanesque churches of the 11th century preserved traits of pre-Romanesque architecture. The churches built in the coastal regions in the 12th and 13th centuries were either three-aisled basilicas with flat wooden ceilings or cross vaults (Cathedral of St. Tripun in Kotor, from 1166) or single-aisled structures with semicircular vaults (Church of St. Paul in Kotor, 1263–66), sometimes surmounted by a dome resting on a low drum supported by squinches or pendentives (Church of St. Luke in Kotor, late 12th century). Covered with pitched tile roofs, such churches often had blank walls, an arched bell tower on the western facade, and a carefully delineated western portal with a rose window above it. The altar section was separated from the rest of the church by a stone barrier decorated with fine carving in which interlace patterns were mingled with zoomorphic and floral motifs echoing classical traditions (Ulcinj, Bar).

While Montenegro was part of the Nemanja kingdom, its interior regions were influenced by the Raška architectural school (*see* SERBIA). The severe single-aisled churches that were built in the Raška style in the 12th and 13th centuries had lateral additions resembling low transepts and domes set on a cubical base (church of the Morača Monastery, 1252). Among the Montenegrin architects who worked in Serbia was Vit of Kotor, who designed the church of the Dečani Monastery. In the coastal architecture of the 14th to 16th centuries individual Gothic elements, such as contours of windows and vaults, were combined with Romanesque forms (churches and houses in Svač, Bar, and Kotor).

The influence of Carolingian art may be seen in the earliest examples of Montenegrin monumental painting, the frescoes in the Church of St. Michael near Ston (11th and 12th centuries), incorporating portraits of the Zeta princes. The pictorial art of the 13th and 14th centuries, blending Romanesque and Gothic elements with Byzantine iconographic motifs, is best exemplified in the Evangelistary of Prince Vukan (1202) and the ciborium in the Cathedral of St. Tripun in Kotor (1362). The frescoes in the church of the Morača Monastery (1252), similar to Serbian art, are notable for their refined and expressive linear style.

The Ottoman invasion and centuries of national oppression had a detrimental effect on the development of Montenegrin culture. Down to the 20th century most towns consisted of a crowded mass of low stone buildings. The Renaissance and baroque styles had little impact on secular architecture, being discernible only in certain details of such structures as the palaces in Kotor, Bar, Perast, and Dobrota. The baroque reached its peak in the 17th and 18th centuries in the churches of Boka Kotorska, designed chiefly by Italian architects. A noteworthy example is the Church at Prčan, begun in 1790. Local architects tended to graft baroque traits onto the Romanesque and Byzantine traditions, as illustrated by the church of the Sava Monastery near Herceg Novi (1777–99, N. Foretić).

The leading painters of the 15th and 16th centuries, Lovro Marinov and Vicko Dobričević, working mainly in Dalmatia, assimilated Renaissance trends. Another major painter of this period was T. Vuković. Baroque sculpture, both altar reliefs and statues, was generally produced by foreign artists. Outstanding local painters of the 17th to 18th centuries included Dj. Mitrofanović, A. Vujičić, and T. Kokolja, who executed wall paintings, pictures, and portraits in the style of the late Venetian Renaissance. The painters of the Rafailović family combined late Byzantine traditions with baroque techniques. Even miniature painting followed late Byzantine canons down to the 19th century.

After the liberation of Montenegro from Ottoman oppression in 1878, the local nobility built imposing urban mansions in the late Empire style (Danilov Palace in Cetinje, 1894–95). In the 1870's Podgorica (present-day Titograd) was built on a grid layout. The eclectic style was best represented in the neo-Byzantine Church of St. Nicholas in Kotor (1910). In the cities, architects continued to build simple and severe two- or three-story dwellings of rough stone with tile roofs and small windows and doors.

A national school of art emerged in the second half of the 19th and first third of the 20th centuries. In the portraits, compositions on themes from national history, and genre scenes of P. Poček, A. Bokarić, M. Gregović, and the watercolorist I. Šobajić naïve realism coexisted with academicism. In the 1920's and 1930's, M. Milunović and P. Lubarda produced landscapes and genre scenes in the style of post impressionism. The line engravings and paintings of I. Novaković reflected a critical view of society. Stylized generalization marked the sculpture of R. Stijović.

A radical change took place in Montenegrin culture after the establishment of people's rule. A new capital, Titograd, was built on the ruins of Podgorica, destroyed during World War II. Town planning was initiated, and model plans for housing projects were developed with the participation of architects from other Yugoslav republics. The housing construction of the late 1950's and 1960's is best exemplified in the five-story modular panel buildings in Titograd. Schools, hospitals, and consumer services establishments were built using prefabricated reinforced-concrete frames.

Along the Adriatic old cities have been modernized, and new cities with comfortable spa facilities have been built, among them Budva, Trsteno, Jaz, Mogren. The old island city of Sveti Stefan has been converted into a hotel-city. Successes have been achieved in the construction of hotels, motels, and administrative buildings using standardized structural elements; examples include the hotels in Cetinje and Herceg Novi, the administrative building in Kotor, and the Beko department store in Titograd. A quest for national distinctiveness characterizes the buildings of the architect S. Radević, noted for their expressive detail, their textural contrasts, achieved by combining concrete with local stone and river pebbles, and their organic link with the landscape (Podgorica Hotel in Titograd).

Significant postwar artworks include the stylistically free landscapes and still lifes of M. Milunović, V. Leković, and A. Prijić; the monuments of L. Tomanović and V. Stanić; and the dynamic and colorful landscapes and historical compositions of P. Lubarda.

Music. Down to the end of the 19th century, Montenegro had only folk music, and to this day the people have preserved the ancient traditions of singing folk epics, heroic songs (to the accompaniment of the *gusle*), lyric songs, and ritual songs. Especially impressive are the dramatic ritual laments, particularly the women's *tužbalice*, and the poetic pastoral lyric songs. There are various types of round dances accompanied by singing, known locally as *oro*. The melodies of Montenegrin songs are characterized by a narrow range, a predominance of archaic tunes in natural modes, a frequent use of mixed or variable meter, and a free rhythmic structure. Most of the singing is polyphonic, often featuring dissonant second intervals.

The first musical societies and performing groups were founded in Montenegro in the last quarter of the 19th century. Army bands were organized by A. Šulc in 1871 and F. Vimer in 1889; the Branko Choral Society was formed in Podgorica (present-day Titograd) in 1892; the Njegoš Choral Society was created in Cetinje in 1908; and the Zahumlje Choral Society was established in Nikšić in 1898. One of Montenegro's first professional musicians was the late 19th-century composer J. Ivanišević, who studied in Prague with Z. Fibich. A music school operated in Cetinje in 1924–25 and from 1932 to 1941.

After World War II a number of music schools were opened, including the Njegoš Music School in Cetinje (founded in 1947 as a primary school and reorganized the next year as a secondary school), the M. Miljanov Music School in Titograd (1950), and the music school in Kotor (1951). Musical life was enriched by the founding of the symphony orchestra and mixed chorus of Radio Titograd and the Oro State Folk Song and Dance Ensemble. Several more music organizations were founded in the 1960's: the amateur Stanko Dragojević Chorus in Titograd, the amateur Nikola Djurković Chorus in Kotor, the Association of Composers and Performing Musicians of Montenegro, and the Union of Cultural and Artistic Societies of Montenegro (Titograd).

E. I. GORDINA

Theater. Traces of ancient dramatized rituals, the exact nature of which is not known, survived in certain folk customs that were practiced down to the first half of the 20th century. An important contribution to Montenegro's theatrical culture was made by Petar II Petrović-Njegoš. His dramatic poem *The Mountain Garland* (1847) and his narrative poem *Tsar Stepan Mali, the Imposter* (1951), based on episodes from Montenegro's historical past, were performed by amateur groups. In addition to amateur productions, Cetinje enjoyed performances by touring companies from Serbia, Croatia, and other regions.

After the liberation of Montenegro from the fascist occupying forces and their collaborators (Dec. 31, 1944), the Montenegro National Theater, comprising an opera and a drama company, was founded in Titograd in 1953. The drama company's repertoire includes Yugoslav and foreign classics, plays by Petar II Petrović-Njegoš, and works by the contemporary Montenegrin playwrights V. Radović and Z. Komanin and by other Yugoslav writers. The company has also staged works by the Russian playwrights N. V. Gogol, A. N. Ostrovskii, and A. P. Chekhov and the Soviet writer A. N. Arbuzov. The company's principal directors are B. Eraković and N. Vavić, and its leading performers are V. Mandić, D. Tomas, Z. Raičević, G. Lengold, P. Begović, D. Malović, B. Vuković, Č. Vukanović, and Z. Stoimirov. Directors from the other Yugoslav republics also participate in the theater's productions.

MOORING EQUIPMENT, the set of fittings and mechanisms aboard a ship that are used to warp and secure the ship when it is moored at a dock, at the wall of a lock, to buoys, or alongside another vessel. A ship's mooring equipment includes mechanisms, such as winches and capstans, that are used to take in and pay out mooring lines, which are ropes or steel cables. It also includes the following fittings: bitts and cleats, around which the mooring lines are made fast; stoppers, which temporarily hold the mooring lines; mooring chocks, rollers, and mooring pipes, which are used to change the direction of the mooring lines; manually operated or mechanized reels, on which the mooring lines are stowed; and line throwers, which throw the mooring lines from the ship.

The present-day level of mechanization in the operations of warping a ship and of taking in, paying out, and making fast the mooring lines is achieved by means of warping winches, which provide constant line tautness and have remote control. Such winches automatically take up slack or, if a mooring line is too taut, pay out line when a ship's position relative to a dock changes during cargo handling, during tides, or because of waves.

The dimensions of individual pieces of mooring equipment and the rate at which mooring lines are taken in are regulated by classification societies. They depend on a ship's area of operation and on the dimensions of the ship and of the ship's superstructures, deckhouses, and other deck structures.

MORUS (mulberry), a genus of trees of the family Moraceae. The trees are 16–35 m tall. The crown is spherical, broadly ovate, and very dense. The bark is brown and cracked. The bare or pubescent ovate leaves have stipules that shed early; their edges are lobate or crenate. The plants are usually dioecious. The flowers are bisexual and gathered in catkins. The fruit—a succulent compound false drupe—measures 1–5 cm in length and is white, pink, dark violet, or almost black.

There are about 24 species, distributed in eastern and southeastern Asia, in southern Europe, in the southern parts of North America, in the northwestern parts of South America, and in parts of Africa. The USSR has four species, in the southern European portion and in Middle Asia. The mulberry tree is cultivated for its leaves, which are used to feed silkworms, and for its fruit. The fruits are sweet or tart, with a sugar content of at least 10 percent. They are eaten fresh or dried, or they are processed into wine. Mulberry wood is strong, resilient, and heavy; it is used as a building and woodworking material.

In the USSR the white mulberry (*M. alba*), *M. bombycus*, and *M. multicaulus* are raised for silkworm cultivation, and the black mulberry (*M. nigra*) is cultivated for fruit. In the USSR local forms, for example, Khasak, Kaichi, and Dzhir, are cultivated as forage crops, as are the new highly productive varieties SANIISh-5, SANIISh-6, SANIISh-7, SANIISh-14, SANIISh-15, SANIISh-17, Tadzhikskaia seedless, Irtyshar, Uzbekskaia, Pionerskaia, Iveriia, Tbilisuri, Ukrainskaia-9, and Ukrainskaia-107. A significant portion of the feed plantings consists of hybrids. For spring feeding of mulberry silkworms the annual branches are cut annually. For summer and fall feedings, the upper third of new shoots is cut. Every four or five years the trees are given a year of rest.

Mulberry trees are drought resistant, relatively undemanding of soils, and salt tolerant. They are not resistant to flooding. Propagation is by seeds, grafts, and layers. The most widespread diseases are bacteriosis, *Cylindrosporium* disease, mildew, root rot, and curl. The most common insect pests are *Apocheima cinerarius, Pseudocaccus comstocki*, mole crickets (*Gryllotalpa*), chafers, wireworms, the mulberry longicorn beetle, and spider mites. (*See also* MULBERRY CULTIVATION.)

MOVING COIL, in low-frequency measurement technology, a component of moving-coil measuring systems that is used in light-beam oscillographs and moving-coil galvanometers. A moving coil is a light coil of wire that is located between the poles of a permanent magnet. In a galvanometer, the moving coil is suspended from very thin metallic ribbons; in an oscillograph, it consists of a very thin wire to which a small mirror is attached.

When a current flows through a moving coil, the coil is deflected in the magnetic field. In moving-coil galvanometers, the magnitude of the deflection is read by means of a microscope. In light-beam oscillographs, it is read on the basis of the deflection of a light beam reflected from the mirror.

MOVING-TARGET INDICATION (MTI), a method of discriminating radio signals reflected from a target against a background of passive interference (*see* RADAR COUNTERMEASURES). The method, which is based on the use of a difference in the speeds of the target and the source of the interference, is employed in coherent-pulse radar sets (*see also* RADAR). When both a useful signal and interference signals are received by an MTI system, the difference in speeds makes it possible to cancel or suppress the interference and preserve the useful signal at the output.

MTI systems are based on the use of memory units. The memory may be an ultrasonic delay line, a visual storage tube, or a shift register. In a very simple system, a difference between signals received in consecutive pulse repetition periods is obtained at the output by means of, for example, an ultrasonic delay line and a subtractor. The subtraction may be carried out at either an intermediate frequency or a video frequency. If the signals are subtracted at a video frequency, phase detection of the signals is used before subtraction. In this case, the signal level at the detector output depends on the phase of a signal with respect to reference oscillations, the phase of which is fixed relative to the phase of the scanning pulses.

Target signals do not appear at the subtractor output, or are canceled, if the target is stationary—that is, is a source of passive interference—or if it moves at a blind speed—that is, moves a distance equal to an integral number of half-waves toward or away from the radar set in a pulse repetition period. However, signals from a target that moves at a speed other than a blind speed are not canceled and will be detected. If the source of the interference is moving, the interference signals may be canceled by introducing the required additional phase shifts into the MTI system.

Besides the blind-speed effect, the factors that reduce the effectiveness of video-frequency MTI include unwanted pulse-amplitude modulation at the system's output. In this case, the modulation frequency is equal to the Doppler frequency if the Doppler frequency is less than half the repetition rate of the scanning pulses. Such modulation is eliminated by means of two quadrature networks with reference oscillations that differ in phase $\pi/2$. The blind-speed effect is controlled by using a variable scanning-pulse repetition period, that is, by wobbulation of the scanning-pulse repetition rate.

The effectiveness of MTI, which is evaluated from the improvement of the signal-to-interference ratio, depends on the speed of the target and the spectrum of the interference. For narrow interference spectra, the effectiveness may be raised by using

several interference cancellation stages. An even higher effectiveness is provided by systems that combine multiple subtraction and weighted signal processing.

L. N. KISLIAKOV [29–218–1]

MUGWORT (*Artemisia vulgaris*), a perennial herbaceous plant of the family Compositae. The usually dark red-brown stems are 30–200 cm tall. The twice- or thrice-pinnatisect leaves are 3–15 cm long and 2.5–20 cm wide; they are broadly ovate or elliptical, white-tomentose beneath, with small auricles at the base. The lower leaves are on petioles; the upper ones are sessile and smaller than the upper ones. The obovate or elliptical heads measure 2–3 mm across and are gathered into a dense panicle. All the flowers are tubular and reddish. The marginal flowers are pistillate, and the middle ones are bisexual. The mugwort is found in forests and steppes in Europe and Western Asia. It grows as a weed along roads and river banks, in wastelands and dumps, amid shrubbery, and—less commonly—in forest glades and margins. In the USSR the plant occurs in the European portion, the Caucasus, Western Siberia, and Middle Asia. Mugwort contains an essential oil, carotene, and ascorbic acid; the apices of the flowering plants and roots are used in folk medicine. [29–252–4]

MUKDEN (also Shenyang), a city in Northeast China, on the Hun Ho (a left tributary of the Liao Ho). Capital of Liaoning Province. Population, 4.2 million (1975). Mukden is the largest railroad hub in Northeast China; two international lines run through the city: Peking-Moscow (via Manchuria station) and Peking-Pyongyang.

Mukden is one of China's most important industrial centers, with a diversified industry. Heavy machine building, including the production of construction and railroad equipment and equipment for the mining, metallurgical, chemical, textile, and food-processing industries, has undergone the most extensive development. The electrical engineering industry produces electric motors, transformers, turbines, diesel engines, electric cable, and electron tubes. In the area of transportation machine building, the city manufactures locomotives, railroad cars, streetcars, and motor vehicles. Other machine-building industries include tractor building, agricultural machine building, and the manufacture of machine tools and electronic equipment.

Metallurgy has undergone extensive development: Mukden has the largest nonferrous metal plant in China and a steel plant. The chemical industry, which produces soda, acids, mineral fertilizers, paints, varnishes, and industrial rubber goods, is also highly developed. As of 1978, a petrochemical plant to be supplied with petroleum from the Tach'ing field was under construction near Mukden, to which a petroleum pipeline has been laid from Tach'ing. The city also has some light industry and paper, printing, wood-products, and food-processing industries. Mukden houses a university. IU. I. GAVRILOVA

Mukden was founded in the second century B.C. as Houch'eng. From the eighth to 13th centuries it was called Shenchou, and under the Yüan Dynasty (13th–14th centuries) it was renamed Shenyang. The Manchus captured the city in 1621, and it bore the Manchu name Mukden from 1625 to 1912; during this period it was known in Chinese as Shengching or Shenyang. The city was the capital of the Manchu state from 1625 to 1644, and under the Ch'ing Dynasty (1644–1911) it was considered the second capital of China. In 1658 it became the capital of Fengt'ien Province and was given the name Fengt'ien.

Mukden was the capital of three northeastern provinces (Manchuria) from 1908 to 1931 and the political and military center of the Fengt'ien clique from 1916 to 1928. Its capture on Sept. 18, 1931, by the Japanese marked the beginning of the Japanese occupation of Northeast China (*see* MUKDEN INCIDENT OF 1931). The city was liberated by the Soviet Army on Aug. 20, 1945. On Nov. 2, 1948, it was liberated from the Kuomintang by the People's Liberation Army of China.

Mukden has a rectilinear street plan. The inner, or Chinese, city (Neich'eng) is a center of commerce and handicrafts with narrow streets that are lined by pisé houses; the remains of a fortress wall have been preserved. West of the inner city is the administrative center, with five- to seven-story European-style buildings and houses surrounded by gardens and parks. In the northern part of the city is the T'iehhsichu, an industrial district in which factory buildings alternate with residential blocks. Palaces and temples of the ninth to 14th centuries are located in the approaches to the city. The Tungpei Museum is located in Mukden. [29–1563–1]

MUKDEN INCIDENT OF 1931, the capture by Japanese troops of the city of Mukden (Shenyang) on Sept. 18, 1931, an event that marked the beginning of the Japanese occupation of Northeast China (Manchuria). As part of a deliberate plan to capture Manchuria, the Japanese imperialists published a false report on Sept. 18, 1931, that the Chinese had destroyed the roadbed of the South Manchurian Railway near Mukden. The same day, under the pretext of protecting the railroad, the Japanese Kwangtung Army seized the city. Taking advantage of the capitulationist policy of China's Kuomintang government and the policy of noninterference of the USA, Great Britain, and the other capitalist powers, the Japanese militarists were able to occupy Manchuria in a few months. They established the puppet state of Manchukuo on the captured territory. Northeast China was liberated from the Japanese by the Soviet Army in August 1945. [29–1564–1]

MUSEUM OF SCIENCE AND INDUSTRY, a cultural and educational institution in Chicago, USA. The museum was founded in 1926 by the American businessman J. Rosenwald, who modeled it after the German Museum. The museum's exhibits demonstrate the latest scientific achievements and their applications in various branches of industry. Special rooms, with a floor space of 500–1,000 sq m, are set aside for exhibits devoted to particular subjects, such as the automobile, electricity, or hardwoods. Notable exhibits include a full-scale coal mine, an operating foundry, an atomic power plant, and a model farm with living quarters, a barnyard, a milking room, a silo, and a hatchery. Many large industrial companies and firms supply exhibits for the museum, which attracts several million visitors annually. [29–561–1]

MUTE SWAN (*Cygnus olor*), a bird of the order Anseriformes. The body measures about 1.5 m in length. The plumage of the adult is white, and of the young, gray. The bill is red, except for the knob at the base and the tip, which are black. The mute swan is found sporadically in Europe, Asia Minor, Middle Asia, and Central Asia. In the USSR it is found in Estonia and Lithuania, along the lower courses of the Danube, Dnestr, and Volga rivers, in southwestern Siberia, and in Kazakhstan, Middle Asia, and Transbaikalia. The mute swan inhabits large lakes with reed thickets. It winters on the Mediterranean, Black, and Caspian seas and in Middle Asia. The clutch contains seven to nine eggs, which are incubated for 35 days. The diet consists of aquatic vegetation. The mute swan is a protected species and hunting is prohibited by law. Domesticated mute swans are found in parks. [29–1220–1]

MUTILATION, in Soviet criminal law, a type of crime committed for the purpose of evading a regular call to active military service (Criminal Code of the RSFSR, art. 80, part 2). In addition, it may be committed by a person subject to military service in order to evade training courses or military registration (Criminal Code of the RSFSR, art. 198-1, part 2), and it may be committed by a person in military service in order to evade the performance of military duties (Criminal Code of the RSFSR, art. 249).

Mutilation is accomplished by the infliction of bodily injury. The guilty person intentionally damages his own health—either by deliberately causing himself some physical injury (for example, by amputating an extremity or harming the organs of sight or hearing) or by unnaturally complicating an existing condition (for example, by irritating a wound). Another form of the crime is requesting or agreeing to the infliction of an injury by someone else; in such cases, those who inflict the harm are held to be accomplices.

The law equates other methods of evading military service with mutilation. Such methods include malingering, exaggerating the

seriousness of a condition, forging documents or using other means of deception, and refusing to bear the obligations of military service.

Evasion of service by military personnel through mutilation or any other means carries the severe penalty of deprivation of freedom for a term of three to seven years. The same act committed in wartime or under combat conditions is punishable by death or deprivation of freedom for five to ten years. Mutilation for the purpose of evading a call to active service carries a sentence of deprivation of freedom for one to five years (Criminal Code of the RSFSR, art. 80, part 2). Mutilation in order to evade military training or registration is punishable by deprivation of freedom for a term of up to three years (Criminal Code of the RSFSR, art. 198-1, part 2). [29–671–2]

NATIONAL LIBERATION FRONT (Ethnikon Apeleutherotikon Metopon; EAM), an organization uniting the patriotic forces of Greece during World War II.

EAM was founded on Sept. 27, 1941, at the initiative of the Communist Party of Greece (CPG). Its principal aims were to liberate Greece from the fascist German occupiers, secure the country's complete independence, and form a provisional government in which each of its constituent political parties would be represented. It wanted the question of the ultimate form of government of Greece to be decided by the Greeks themselves.

EAM organized the Greek resistance movement and, in December 1941, formed the Greek National Popular Liberation Army (ELAS). It was also responsible for the Athens General Strike of 1943. In the same year it laid the foundations for a popular democratic regime in the liberated areas of the country. On Mar. 10, 1944, in accordance with a resolution of the Central Committee of EAM, the Political Committee of National Liberation was established; it in effect performed the functions of a provisional democratic government. By October 1944, when Greece was liberated from the fascist German occupation forces, more than 1.8 million people were united in support of EAM.

On Apr. 24, 1945, EAM became a political bloc of left-wing parties, such as the CPG, the Agrarian Party, and the Democratic Party. An antidemocratic law of Dec. 27, 1947, banned the EAM bloc. [29–1627–3]

NECK, the part of the body between the head and the trunk in man and land vertebrates. The neck is responsible for the mobility of the head, permits orientation in space, and facilitates the grasping of food, defense, and attack.

The framework of the neck consists of cervical vertebrae. The neck muscles are primarily modified portions of the truncal musculature. In amniotes, a compressor of the neck has developed—a derivative of the voluntary visceral musculature. The neck contains the initial sections of the respiratory system (larynx, trachea) and digestive system (pharynx, some salivary glands, part of the esophagus), several blood vessels (for example, the carotid arteries and jugular veins) and lymphatic vessels, the thyroid and parathyroid glands, and nerves. The initial segment of the spinal cord lies in the cerebrospinal canal, enclosed by arches of the cervical vertebrae.

In amphibians, the neck is not outwardly noticeable (there is only one vertebra), and the head can move only up and down and a little to the sides. In amniotes, the cervical portion has several vertebrae, and the development of the atlas and epistropheus (axis) enables the head to bend and rotate. In birds, the number of cervical vertebrae varies from nine to 25, and the combination of their movements makes it possible for some birds to rotate their heads 270° in one direction. In mammals, the cervical portion, regardless of the length of the neck, usually contains seven vertebrae. This is also true of the whale, whose neck is not outwardly separate, and of the giraffe. In the case of secondary limitation of neck mobility, the vertebrae of the cervical segment fuse (in cetaceans, armadillos, jerboas, and some other animals). [29–1170–5]

NEMIROVICH-DANCHENKO SCHOOL-STUDIO (full name, Vl. I. Nemirovich-Danchenko School-Studio of the M. Gorky Moscow Art Theater of the USSR), the highest theatrical educational institution in Moscow. The school-studio was organized in 1943 to train actors using the ideological-creative principles of the school of the Art Theater and the system of K. S. Stanislavsky. I. M. Moskvin, N. P. Khmelev, V. G. Sakhnovskii, and I. Ia. Gremislavskii were important in its founding. The school has two departments—one to prepare actors for work in motion pictures and the theater and one to train stage designers and technicians; an evening division of the latter department was opened in 1961.

Outstanding teachers at the school have included M. N. Kedrov, V. Ia. Stanitsyn, A. K. Tarasova, V. O. Toporkov, I. M. Raevskii, V. A. Orlov, A. M. Karev, G. A. Gerasimov, B. I. Vershilov, and A. N. Gribov. The current teaching staff includes A. I. Stepanova, P. V. Massal'skii, O. N. Efremov, E. N. Mores, V. P. Markov, S. S. Piliavskaia, E. A. Evstigneev, V. V. Shverubovich, and professors V. Z. Radomyslenskii, A. Ia. Zis', and V. Ia. Vilenkin.

The school has produced such highly qualified teachers as V. K. Moniukov, V. N. Bogomolov, I. M. Tarkhanov, O. G. Gerasimov, N. P. Alekseev, A. N. Petrova, O. Iu. Frid, M. M. Kunin, E. P. Freze, A. N. Ponsov, K. N. Golovko, and E. V. Radomyslenskii.

In the 1977–78 academic year the school-studio had 251 students and 57 teachers, including 11 professors and doctors of sciences and 21 docents and candidates of sciences. Graduates of the acting department, including A. V. Batalov, E. Ia. Urbanskii, L. I. Gubanov, and V. S. Davydov, have formed the core of the companies of the Moscow Art Theater, the Sovremennik Theater, and the young people's New Drama Theater-Studio and have contributed several artists to the company of the Mayakovsky Theater and many theaters of Moscow, Leningrad, and other cities of the USSR.

The school has a scientific research section, which studies and publishes the legacy of Stanislavsky and Nemirovich-Danchenko, the founders of the Moscow Art Theater. The section has prepared and published such works as *The Collected Works of K. S. Stanislavsky* (vols. 1–8, 1954–61), *The Life and Works of K. S. Stanislavsky: A Chronicle in Four Volumes, 1863–1938* (1971–76), and *The Days and Years of Vl. I. Nemirovich-Danchenko: A Chronicle of His Life and Works* (1962).

N. P. ALEKSEEV [29–1266–3]

NET OUTPUT, the part of the gross product that remains after subtracting the means of production consumed in the production process—raw materials, supplies, fuel, and power—and the amortization of fixed production assets. From the standpoint of the formation of value, net output is value newly created in the branches of material production ($v + m$). The total net output of all branches of material production constitutes the national income of society.

Net output is calculated for the various branches of material production, such as industry, construction, and agriculture. In industry, it is calculated as the difference between gross output and material production costs. In this calculation, the gross product of industry is based on industry's prices, that is, the turnover tax is included. Net output is needed to calculate national income and to compile the balance of the national economy of the USSR. The net output of some branches of industry and enterprises may also be calculated on the basis of wholesale prices of enterprises —that is, exclusive of the turnover tax.

Net output in construction is calculated as the difference between the gross product of construction on the one hand and the material costs of construction and the capital repair of buildings and structures on the other. The gross product of construction is the value of work performed in new construction, in the expansion and modernization of existing enterprises, and in the capital repair of buildings and other structures. The material costs of construction include the cost of construction materials used, such as structures and units, fuel, and electric energy; the capital repair of buildings and structures involves the amortization of construction machinery and other fixed capital of construction organizations.

The net output of agriculture is the difference between the gross product of agriculture, calculated on the basis of gross turnover (including the value of output produced and consumed on

the farm), and material production costs, whose value includes both raw materials and supplies purchased from outside sources and products produced on the farm, such as seed and fodder. Net output in other branches of material production is calculated as the difference between gross output and material production costs, with allowance made for the specific features involved in calculating these indicators in a given branch.

The net output of various branches of material production is calculated by state statistical agencies: the Central Statistical Board of the USSR and the central statistical boards of the Union republics. The calculations are made in terms of the prices actually in effect in a given year and in terms of comparable prices. Expressing net output in comparable prices provides a picture of its development. In the production method of calculation, a figure for net output in comparable prices is arrived at by subtracting material production costs (in comparable prices) from the gross product. In the distribution method, net output is calculated as the sum of wages (and other types of remuneration for labor), profits, the turnover tax, and other elements that make up net income. This method of calculation tests the accuracy of calculations based on the production method.

In 1976 the net output of industry, including the turnover tax, accounted for 52.6 percent of the national income created in branches of material production; the net output of agriculture, 16.5 percent; the net output of construction, 11.2 percent; the net output of transportation and communications, 6.3 percent; and the net output of the remaining branches, 13.4 percent.

M. R. EIDEL'MAN [29–638–2]

NET PROFIT, in capitalist society, the profit left over after income taxes. Net profit, whose amount depends on the amount of gross profit and the magnitude of income taxes, is used by businessmen and monopolies for the expansion of production and for parasitic consumption. By maintaining secrecy in commercial operations, exaggerating the depreciation rate of fixed assets, and using sophisticated methods to falsify accounts, capitalists are able to understate their net profit and thereby pay lower taxes.

The net profit of socialist enterprises is the profit shown on the balance sheet—that is, the amount left over after subtracting payments made to the state from profits: capital charges, fixed (rent) payments, payments from the free profit remainder, and interest payments on loans. Net profit is used to form incentive funds, to augment the circulating capital of enterprises, and to finance certain capital investments. [29–638–1]

NET SOCIAL INCOME, a part of national income that takes the form of surplus product. The division of national income into necessary and surplus product is an objective economic necessity irrespective of the mode of social production. The ways of forming the net social income and the principles underlying its distribution and use are determined, however, by the socioeconomic conditions of reproduction.

Under capitalism, the net social income takes the form of surplus product and a corresponding surplus value. K. Marx, analyzing the reproduction of the total social product and its individual elements, revealed the essence of the net social income, under the capitalist mode of production, as an economic category. "The net . . . income is the surplus value—and therefore the surplus product—that remains after deducting wages; it represents the surplus value realized by capital and to be divided with the landlord and the surplus product measured by this surplus value" (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 25, part 2, p. 409).

Under capitalism, the net social income is a product of exploitation of the working people. As Marx noted, "Surplus labor in general, as labor performed over and above the given requirements, must always remain. In the capitalist as well as in the slave system it merely assumes an antagonistic form and is supplemented by complete idleness of a stratum of society" (*ibid.*, pp. 385–86). In the process of distribution, the net social income of capitalist society appears in two basic monetary forms: profit and rent.

Under socialism, the net social income, as an expression of the surplus product, does not become surplus value but is used in the interests of the society as a whole. "Even though all surplus value is represented in some surplus product, the surplus product in itself, on the contrary, does not represent surplus value" (*ibid.*, vol. 26, part 3, p. 383). In accordance with the two forms of socialist ownership, the net social income comprises the net income of the state (public) sector and the net income of the cooperative and collective-farm sector. Both net incomes are created at socialist enterprises and in socioeconomic terms are essentially the same.

The net social income created in the state sector takes the following monetary forms: the turnover tax, the profit of enterprises (associations) from production and economic activity, and the payments of enterprises (associations) to the social insurance fund. In the cooperative and collective-farm sector, unlike the state sector, the net social income has both a monetary and physical aspect. The monetary part of net income is profit realized from the sale of commodity output. The other part of net income represents payments in kind consumed within the kolkhoz economy: seed, fodder, young livestock to be fattened, and insurance funds.

As the net income of socialist society is distributed, redistributed, and used, it is broken down into two parts—centralized and decentralized net income—with the help of the financial mechanism and prices. The centralized net income of the state includes the turnover tax, payments by state enterprises (associations) from profits (for example, capital charges, fixed payments, rent payments, and payments from the free profit remainder), and payments into the social insurance fund.

Kolkhozes and cooperatives augment the centralized fund through their income tax payments and insurance payments. The state disburses the centralized net income on a planned basis to meet public needs: the financing of the national economy, the defraying of expenditures on defense and administration, and the creation of social consumption funds and reserve funds. Some of the net social income remains at the disposal of state enterprises, cooperatives, and kolkhozes and is used, on a decentralized basis, to finance some capital investments, to augment current capital, to pay loan interest, to improve production technology, to augment indivisible funds, and to form incentive funds. Such a system of distribution, redistribution and utilization of the net income of socialist society is in keeping with the principles of democratic centralism and the profit-and-loss method of management.

NIELLO, an alloy of silver, lead, sulfur, and other elements used to decorate metal articles, mainly of silver. The alloy, in powder form, is placed on the engraved surface of the metal; the object is fired, and then a black or dark gray pattern, firmly fixed to the base, appears on the object.

Niello on silver and other metals was used in antiquity. Thematic, landscape, and purely ornamental pictures were executed in niello on separate plates in Italy in the 15th and 16th centuries. Niello was used in Western Europe, India, and the Baltic region to decorate everyday objects (dishes, cutlery, boxes), weapons, and jewelry. Ornamental niello tracery was commonly used to decorate silver in the countries of the Middle East and the Caucasus. Russian craftsmen of the tenth to 13th centuries decorated silver pendants, bracelets, and lunulae with niello. The art was widely used by Russian craftsmen of the 15th and 16th centuries; niello was particularly popular in the 18th century in Velikii Ustiug (*see* VELIKII USTIUG NIELLO WORK IN SILVER). Niello is currently widely used in Kubachi for artistic metalworking.

NIGELLA, a genus of annual herbaceous plants of the family Ranunculaceae. The leaves are usually twice or thrice pinnati-

sect, with narrow lobes. The flowers are generally solitary and regular. There are five petaloid sepals; the petals are small and in the form of two-lipped nectaries. The multiple fruit consists of five (or ten) fused follicles. The seeds are black.

There are approximately 25 species, distributed mainly in the Mediterranean region and Southwest Asia. The USSR has 11 species, growing in steppes, in weedy areas, and amid crops in the European portion, the Caucasus, and Middle Asia. The most common species are the fennel flower (*N. sativa*) and love-in-a-mist (*N. damascena*). The former is raised for its seeds in the Middle East, the Mediterranean region, the southern portion of Western Europe, and the USSR (central regions of the European USSR and—less commonly—the Northern Caucasus). The seeds are used as a spice. Love-in-a-mist, an ornamental with blue-violet or white flowers hidden among slightly dissected apical leaves, is also grown in many countries for its seeds. Many species of *Nigella* are nectar-bearers. [29–304–2]

NOISE, random vibrations of varying physical nature, which are distinguished by a complex temporal and spectral structure. In everyday life "noise" implies various undesirable acoustical disturbances during the apperception of speech or music, as well as any sounds that interfere with rest or work. Noise plays a significant role in many areas of science and technology, such as acoustics, radio engineering, radar technology, radio astronomy, information theory, computer technology, optics, and medicine.

Regardless of its physical nature, noise differs from periodic vibrations in the random change in the instantaneous values of the quantities characterizing a given process. Often, noise is a mixture of random and periodic vibrations. Depending on the temporal, spectral, and spatial structure of noise, various mathematical models are used to describe it. Averaged parameters determined on the basis of statistical laws that take into account the structure of noise at the source and the properties of the medium in which the noise is propagated are used for the quantitative evaluation of noise.

Noise is subdivided into statistically stationary and nonstationary noise. The theory and methods of measuring stationary noise, the classical model of which is white noise, are most highly developed. Stationary noise is characterized by the constancy of the average parameters: intensity (power), spectral distribution of intensity (spectral density), and the autocorrelation function (the time-averaged product of the instantaneous values of two noises shifted by the delay time). The noise observed in practice, which results from the action of many independent sources, such as the noise of a crowd of people, the sea, tools, or a vortex air flow or the noise at a radio-receiver output, is quasi-stationary. Noise that lasts for short time intervals (shorter than the averaging time in the measuring devices) is called nonstationary noise. Such noise includes, for example, the street noise of passing traffic, individual sounds in production processes, and infrequent impulse noise in radio engineering.

The investigation of noise pursues varied objectives: the study of noise sources in order to reduce their adverse effect on man and various systems; the search for methods and means of optimal reception, detection, and measurement of the parameters of various signals in the presence of noise; and the improvement of the accuracy of measurements in analog and digital data-processing devices. Sound-level meters, frequency analyzers, correlators, and other devices are used to measure the characteristics of noise.

Any vibrations in solids, liquids, and gases may be sources of audible and inaudible acoustical noise. In technology, the main sources of noise are various engines and machinery. An elevated noise level in machinery and mechanisms is often an indication of malfunction or design inefficiency. The precise fabrication and adjustment of parts and the dynamic balancing of all moving parts lead to a reduction in noise and, in general, to the reduced wear of parts and increased operating life and precision of operation.

Radio-electronic noise—random fluctuations of currents and voltages in electronic devices—results from the nonuniform emission of electrons in electronic vacuum devices (shot noise, the flicker effect), from the nonuniformity of the processes of generation and recombination of charge carriers (conduction electrons and holes) in semiconductor devices, from the thermal motion of charge carriers in conductors (thermal noise), and from the heat radiation of the earth, the earth's atmosphere, the planets, the sun, stars, the interstellar medium, and other objects (cosmic noise). Noise limits the sensitivity of radio receivers.

In many cases, noise is used as a source of information. For example, in naval technology, submarines and surface vessels are detected and their positions fixed from the noise they generate when moving. In radio astronomy, the radio-frequency radiation of stars and other cosmic formations is investigated on the basis of noise in certain frequency ranges. Noiselike signals are used in the technology of radio and acoustical measurements, for example, in architectural acoustics. Some sounds in music are by their physical nature noise or have noiselike features. The voiced consonants encountered in speech are also noise in their properties.

The qualitative features of sensation during the perception of acoustical noise by the hearing organs and the organism as a whole depend on the intensity (*see* LOUDNESS) and spectral composition of the noise. The adverse effect of noise on the human organism is manifested in specific damage to the hearing organs and nonspecific changes in other organs and systems of the body. The character, level, and frequency composition of noise are major factors, as are the length of exposure to noise and individual sensitivity. Prolonged exposure to intense noise may considerably disrupt the activity of the central nervous system, vascular tonus, and the functions of organs of the gastrointestinal tract and endocrine system, as well as gradually lead to hardness of hearing owing to neuritis of the vestibulocochlear nerve. An initial disruption of the perception of high frequencies (4,000–8,000 Hz) is characteristic of occupational hardness of hearing. The nonspecific action of noise may be manifested before any actual changes in hearing occur and is expressed as neurotic reactions, asthenia, and disruption of the functions of the autonomic nervous system. Coordination of movements is disrupted and labor productivity is reduced under the influence of noise. The term "noise disease" has appeared in the medical literature in connection with the unified etiology of the clinical disturbances.

A number of organizational, technical, and medical measures are implemented to prevent the adverse effects of acoustical noise on the human organism. The factors that produce noise are eliminated or weakened at the source. The propagation of noise from noise sources is prevented by insulation of noisy machinery assemblies against noise, installation of shock absorbers, and sound absorption, which attenuates noise by reducing reflections from surrounding design elements lined with sound-absorbing porous materials. Aerodynamic noise (for example, exhaust and noise in air ducts) is reduced by eliminating the causes of vortex formation, insulating air ducts against noise, and employing noise suppressors. It is important to alternate efficiently the work and rest periods of persons working under noisy conditions, to limit the length of their exposure to noise, and to monitor their health. The control of street noise is effected by replacing streetcars with trolleys and buses, restricting the use of horns, and other measures. Zones where noise levels reach 85 decibels are marked with warning signs, and people working in these zones are provided with individual sound-insulating earmuffs. Apart from the adverse effects of noise on man, some acoustical noise, such as the noise of the surf and forests, is known to have a healthful, relaxing effect.

NOISE, ATMOSPHERIC, electrical fluctuations in a receiving antenna caused by the heat radiation of the earth's atmosphere in the radio spectrum (*see* FLUCTUATIONS, ELECTRICAL).

Atmospheric noise worsens the quality of radio reception by engendering acoustical noise and false signals and decreasing measurement accuracy. A quantitative characterization of atmospheric noise is provided by noise temperature, which is equal to the product of the average physical temperature of the atmosphere (≈300°K) and the coefficient of absorption of the atmosphere. The latter depends on the state of the atmosphere (humidity, dust content, and the like), the shape of the antenna radiation pattern, the working length of the wave λ, and the orientation of the antenna in space. Ordinarily, when $\lambda > 10$ cm and altitudes of the main lobe of the radiation pattern are more than 20°, atmospheric noise is negligibly small. [29–1547–1]

NOISE, RECEIVER, the electrical fluctuations that occur mainly in the input circuits (for example, amplifiers and filters) of radio-receiving apparatus (*see* FLUCTUATIONS, ELECTRICAL).

When combined with noises from external sources, such as atmospheric noise, terrestrial noise, and cosmic noise, a total noise is produced that acts as a natural threshold of the sensitivity of the radio receiver. The quantitative characteristic of receiver-noise intensity is its noise temperature. For example, until the 1950's, the input devices used in superhigh-frequency radio receivers had noise temperatures of more than 2000°K, which was many times higher than the noise temperatures of the external sources. Subsequently, low-noise, superhigh-frequency amplifying devices were invented, such as tunnel diodes, parametric amplifiers, and quantum mechanical amplifiers, which made it possible to lower the receiver-noise temperatures, respectively, to values of the order of 300°, 30°, and 3°K, thereby improving the sensitivity of superhigh-frequency radio receivers by about 10 to 50 times.

I. M. AINBINDER [29–1546–5]

NOISE, TERRESTRIAL, electrical fluctuations in a receiving antenna caused by the heat radiation of the earth in the radio spectrum, which, like atmospheric noise, worsen the quality of radio reception (*see* FLUCTUATIONS, ELECTRICAL).

A quantitative characterization of terrestrial noise is given by the noise temperature, which is equal to the product of the physical temperature of the absorbing layer of the earth (≈300°K) and the coefficient of absorption of this layer. The latter depends on the orientation of the antenna with respect to the earth. Terrestrial noise is comparatively great at small altitudes of the main lobe of the radiation pattern of a high-directional antenna placed on the earth and in those cases where an antenna mounted on a low-flying object is directed at the earth. If the main lobe is directed at the zenith, terrestrial noise is usually negligible.
[29–1547–2]

NOISE CONTROL, the aggregate of measures (technical, architectural, acoustical, and the like) that provide protection from noise and limit noise levels in rooms, buildings, and populated areas in accordance with established medical standards. Effective noise control can greatly enhance the public service planning of populated areas and make the living, working, and recreational conditions healthier for the inhabitants. (*See also* ACOUSTIC MATERIALS; SOUNDPROOFING; SOUND-ABSORBING STRUCTURES; and CONSTRUCTION ACOUSTICS.) [29–1543–1]

NOISE FIGURE (or noise factor), the numerical characteristic of a radio receiver that indicates how much its sensitivity to an incoming signal is decreased by the effects of its internal noise (*see* FLUCTUATIONS, ELECTRICAL).

The noise figure F is equal to the ratio of the total noise power at the output of an actual receiver P_{act} to the output noise power of a similar ideal (noiseless) receiver P_{id} under the condition that the only source of input noise in both cases is the thermal noise of the matched impedance (dummy antenna) at the temperature $T_0 = 290°K$ (*see* NYQUIST FORMULA):

$$F = P_{act}/P_{id} = P_{act}/kT_0\Delta fG \quad (1)$$

Here, k is Boltzmann's constant, Δf is the receiver's passband in hertz, and G is the receiver's power gain. The noise figure is also expressed in decibels: $F\,(dB) = 10 \log F$. For an ideal receiver, $F = 1$ (or 0 dB), while for an actual receiver, $F > 1$. Often, the noise figure is described by the noise temperature T_n.

The noise figure is measured by means of standard noise generators or standard signal generators by determining how much the total power of the receiver's output signal is increased with a calibrated signal P_{gen} at its input compared with the output power without the signal. When measuring by the "twofold excess" method, P_{gen} is adjusted so that the output-signal power is doubled. Then, $P_{act} = GP_{gen}$, and the noise figure is calculated from equation (1).

Quantum mechanical amplifiers and cooled parametric amplifiers using semiconductor diodes, for which $F \approx 1.1$ and $T_n \approx 30°K$ (when not cooled, $F \approx 1.3$ and $T_n \approx 100°K$), have the lowest noise figures. For amplifiers using traveling-wave tubes and tunnel diodes, $F \approx 3$ to 10 and $T_n \approx 600°$ to 3000°K. Radio and television receivers have noise figures ranging from several units to several tens.

NOISE TEMPERATURE, an effective quantity that serves as a measure of the noise power in radio receivers. The noise temperature T_n is equal to the temperature of the matched impedance (the dummy antenna) at which its thermal noise power is equal to the noise power of the given device. The ratio T_n/T_0 ($T_0 = 290°K$) is called the relative noise temperature.

The concept of noise temperature is used in radio engineering to estimate the noise of electronic and semiconductor devices that are designed for the amplification and conversion of electric signals. In radio astronomy it is used to describe sources of cosmic radio-frequency radiation. It is also used to determine the noise contribution made by a radio receiver to the useful signal in the course of its processing. The noise figure (or noise factor) F, which is related to T_n by the equation $T_n = (F - 1)T_0$, is also used in the last case.

The noise temperature of an actual object is usually determined by comparing it with the noise temperature of a given standard noise generator.

NOTOSTRACA, a suborder of invertebrates of the order Phyllopoda. Almost the entire body is covered with a broad carapace. A pair of closely placed compound eyes and an unpaired simple eye are grouped in the front of the carapace. There are no fewer than 40 pairs of thoracic phylloid appendages, the first two pairs of which are equipped with long filiform tactile processes. The abdomen consists of many segments and ends in a pair of long filiform processes.

The Notostraca inhabit shallow bodies of fresh water that dry up seasonally. They feed on decaying organic remains, plants, and small animals. The females lay eggs into pouches on the 11th appendages and release the eggs on the bottom. The eggs can withstand high and low temperatures in the course of several years. Males are considerably less common than females.

The subphylum embraces nine genera. In the USSR the most

common are *Lepidurus apus*, which measures as much as 12 mm in length, and *Triops cancriformis*, which measures as much as 7.5 cm in length. Some species serve as food for fish and swimming birds. Others are pests in rice fields, uprooting seedlings and eating shoots.

The Notostraca are considered very old. They have been in existence since the Triassic.

NUMBER, in linguistics, the grammatical category indicating the number of participants in an action—subjects and objects—through morphological means. The primary distinction in the category of number is between singular and plural. Some languages also have a dual number and, more rarely, a triple number. In the historical development of a language, the dual may weaken and be absorbed by the plural, as happened in the Slavic languages; for example, in the second person personal pronoun Old Church Slavonic distinguished singular (*ty*, "thou"), dual (*va*, "you two"), and plural (*vy*, "you").

The forms and meanings of the plural include the distributive plural, which indicates that plurality is thought of as consisting of individual objects (*listy*, "leaves"), and the collective plural, which indicates that plurality is thought of as a single aggregate (*list'ia*, "leaves"). Collective meaning can also be expressed by a singular form (*triap'e*, "rags," *voron'e*, "crows"). Plural forms can also indicate the concept of class (generic plural) (*v etoi mestnosti vodiatsia volki*, "there are wolves in this area"). Plural forms may sometimes be used with the meaning of the singular, such as the polite, or honorific, form of the second person personal pronoun (*vy*, "you," in addressing one person) and the plural form in the first person (*my*, "we") as used in the speech of sovereigns.

Number is an independent category in nouns and personal pronouns. Other parts of speech, including verbs, adjectives, and the other types of pronouns, acquire marking for number through agreement (syntactic number). Number agreement is obligatory in the Indo-European languages (*on rabotaet*, "he works," *oni rabotaiut*, "they work"). However, as morphology becomes simpler, agreement may also disappear. For example, in English there is no number agreement between adjective and noun ("clever child," "clever children"). There are various ways of expressing plural number: affixation (*stol*, "table," *stoly*, "tables"), suppletion (*chelovek*, "person," *liudi*, "people"), internal inflection (Arabic *radžulun*, "man," *ridžālun*, "men,"), in which the root vowel changes, and reduplication (Indonesian [Malay] *orang*, "person," *orang-orang*, "people"). In Indo-European languages the plural form is required if a noun is modified by a word denoting quantity (*desiat' knig*, "ten books," *mnogo knig*, "many books"); in other languages the noun may have the form of the singular in such constructions (Hungarian *könyv*, "book," *tiz könyv*, "ten books," *sok könyv*, "many books"). In many Asian and American languages the plural of nouns used in constructions containing a numeral is expressed by means of special classifiers, which differ according to the lexical group to which the noun belongs. In such instances the nouns do not change their form (Vietnamese *hai con meo*, "two cats," where *con* is the classifier).

NUMBER, the most important mathematical concept. The concept of number arose in simplest form in primitive society and over the ages has undergone changes, gradually growing richer in content with the expansion of the range of human activities and the range of problems requiring quantitative description and investigation. In the first stages of development, the concept of number was determined by the requirements of counting and measurement in man's daily activities. Subsequently, number became the basic concept of mathematics, and the further development of the concept has been determined by the needs of mathematical science.

The concept of natural number, or positive integer, arose as far back as prehistoric times in connection with the need to count objects. In general, its formation and development proceeded as follows. At the lower stage of primitive society, the concept of abstract number was nonexistent. This did not mean that primitive man was unable to ascertain the number of objects in a given set, such as the number of people involved in a hunt or the number of lakes in which fish could be caught. However, the consciousness of primitive man still could not perceive that which was common to various groups of objects, such as "three people" or "three lakes." Analyses of the languages of primitive peoples have shown that different phrases were used in counting different objects. The word "three" was conveyed differently in the contexts of "three people" and "three boats." Of course, such named number series were very short and terminated in a nonindividualized concept ("many") of a large number of some object, which was also named, that is, expressed by different words for different kinds of objects, such as "crowd," "herd," and "pile."

The concept of abstract number emerged out of the primitive way of counting objects, consisting in comparing the objects of a given specific set with objects of some defined set that acts as a standard. Among most peoples, fingers served as the first such standard ("finger counting"), confirmed by linguistic analyses of the names of the first numbers. At this stage, number becomes abstract, independent of the nature of the objects being counted, and at the same time acts as a fully concrete embodiment associated with the nature of the reference set. The expanding needs of counting forced people to use other counting standards, such as notches on sticks. For recording comparatively large numbers, a new idea came to be used—the designation of some specific number (ten among most peoples) by a new symbol, for example, a notch on a different stick.

With the development of writing, the possibilities of reproducing numbers expanded significantly. At first, numbers were denoted by lines on the writing material, such as papyrus or clay tablet. Later, other symbols were introduced to denote large numbers. The Babylonian cuneiform notations for numbers, like the Roman numerals that have been preserved to this day, clearly show that it was precisely in this manner that number notation developed. A major step forward was the Hindu positional numeration system, which made it possible to write any natural number by means of ten symbols—digits (*see* NUMERATION SYSTEM). Thus, as writing developed, the concept of natural number assumed increasingly abstract form. Also, the abstract concept of number, expressed by special words in speech and denoted by special symbols in writing, became increasingly entrenched.

An important step in the development of the concept of natural number was the recognition of the infiniteness of the sequence of natural numbers, that is, the possibility of its unlimited continuation. A clear understanding of the infiniteness of the sequence of natural numbers is reflected in Greek mathematical works (third century B.C.), specifically in Euclid's and Archimedes' works. The unlimited continuability of the sequence of prime numbers is established as early as Euclid's *Elements*, and the principles for the construction of names and symbols for any large number, particularly numbers larger than the "number of grains of sand in the world," are given in Archimedes' book *Sandreckoner*.

Operations on numbers came into use with the development of the concept of natural number in connection with the counting of objects. The operations of addition and subtraction originally arose as operations on sets themselves, in the form of the joining of two sets into one and the separation of part of a set. Multipli-

cation, apparently, arose as a result of counting in equal parts (by twos or threes, for example), and division arose as the division of a set into equal parts (*see* MULTIPLICATION and DIVISION). The abstract nature of these operations became evident after centuries of experience, as did the independence of the quantitative result of an operation from the nature of the objects forming the set, for example, that two objects and three objects will add up to five objects, regardless of the nature of the objects. Only then did mathematicians begin to develop the rules of operations, to study the operations, and to devise methods of solving problems; in other words, only then did the development of the science of numbers—arithmetic—begin (*see* ARITHMETIC). Arithmetic developed above all as a system of knowledge with an overt practical orientation. However, in the very process of its development, it became evident that there was a need to study the properties of numbers as such and to elucidate the increasingly complex regularities in their interrelations brought about by the very existence of the operations. The refinement of the concept of natural number began, and various classes, such as even and odd numbers and prime and composite numbers, became distinguished. The study of the deep-seated regularities of the natural numbers continues and constitutes the branch of mathematics known as number theory (*see* NUMBERS, THEORY OF).

Natural numbers, in addition to their primary function of characterizing the number of objects, have another function, that of characterizing the order of objects in a sequence. The concept of ordinal number (first, second, and so on), which arises in connection with this function, is closely linked with the concept of cardinal number (one, two, and so on). In particular, the most frequently used method of counting objects since time immemorial has been the placement of the objects being counted in a sequence and then counting them using ordinal numbers (for example, if the last object being counted is seventh, then the total number of objects is seven).

The question of substantiating the concept of natural number is rather recent. The concept is so familiar and simple that the need for its definition in terms of some simpler concepts never arose. It was only in the mid-19th century, under the influence of the development of the axiomatic method in mathematics, on the one hand (*see* AXIOMATIC METHOD), and the critical reassessment of the foundations of mathematical analysis, on the other, that the time became ripe for substantiating the concept of cardinal natural number. A clear definition of the concept of natural number based on the concept of set (an aggregate of objects) was provided in the 1870's by G. Cantor. First, Cantor defines the concept of the equivalence of sets. Specifically, two sets are said to be equivalent if the objects of the sets can be put into one-to-one correspondence. Then the number of objects within a given set is defined as that which the given set and any other set of objects equivalent to it have in common. The definition reflects the essence of the natural number as that which results from counting the objects composing the given set. Indeed, at all historical levels, counting has consisted in comparing one by one the objects being counted with the objects constituting a "reference" set (in the early stages, the fingers of the hands and notches on sticks; today, words and symbols representing numbers). Cantor's definition was the starting point for the extension of the concept of cardinal number from finite to infinite sets.

Another substantiation of the concept of natural number is based on an analysis of the relation of succession, which, it turns out, can be axiomatized. A system of axioms constructed on the basis of this principle was formulated by G. Peano.

It should be noted that the extension of the concept of ordinal number to infinite sets (transfinite ordinal numbers and, more generally, ordinal types) diverges sharply from the generalized concept of cardinal number, since quantitatively identical (equivalent) sets can be ordered by different methods. (*See* TRANSFINITE ORDINAL NUMBER and SET THEORY.)

Historically, the first extension of the concept of number was the introduction of fractions. The first use of fractions was connected with the need to carry out measurements. The measurement of some quantity consists in comparing it with another qualitatively similar quantity, which is taken as the unit of measurement. This comparison is performed by means of the operation—specific to the method of measurement—of "applying" the unit of measurement to the quantity being measured and counting the number of such applications. Length is measured in this way by applying a segment that is taken as the unit of measurement, and the amount of a liquid is measured by means of a measuring vessel. However, the unit of measurement does not always fit the quantity being measured a whole number of times, a fact that cannot always be ignored, even in the most primitive practical activity. Herein lies the source of the simplest and most "convenient" fractions, such as one-half, one-third, and one-fourth. It was only with the development of arithmetic as the science of numbers that the idea emerged of considering fractions with any natural denominator, as well as the concept of fractional number as a quotient in the division of two natural numbers, of which the dividend is not divisible by the divisor (*see* FRACTION).

The further extension of the concept of number was now no longer connected with the direct needs of counting and measurement but was a direct consequence of the development of mathematics.

The introduction of negative numbers was brought about of necessity by the development of algebra as the science providing general methods for the solution of arithmetic problems, regardless of content or given numerical data. The need for negative numbers in algebra arose in the solution of problems that reduce to linear equations with one unknown. A possible negative answer in problems of this kind may be interpreted by using as examples very simple directed quantities (oppositely directed segments, motion in the direction opposite to the direction chosen, property-debt). However, in problems that involve the repeated application of the operations of addition and subtraction, a great many cases must be considered in the course of a solution if negative numbers are not used, which may prove to be so burdensome a task that the advantage of an algebraic solution over an arithmetic solution is lost. Thus, the extensive use of algebraic methods in solving problems is extremely difficult unless negative numbers are used. In India negative numbers were used systematically as early as the sixth to 11th centuries in problem solving and were interpreted basically as they are today.

In European science the use of negative numbers did not become firmly established until the time of R. Descartes, who provided geometrical interpretation of negative numbers as directed line segments. Descartes's creation of analytic geometry, which made it possible to consider the roots of an equation as the coordinates of the points of intersection of some curve with the axis of abscissas, at long last eliminated the fundamental difference between the positive and negative roots of an equation, since their interpretation proved to be essentially the same.

Integers and fractions, both positive and negative, as well as the digit zero, were grouped under the general term "rational numbers." The set of rational numbers is said to be closed with respect to the four arithmetic operations. This means that the sum, difference, product, and quotient (except the quotient in division by zero, which is meaningless) of any two rational numbers is also a rational number. The set of rational numbers is ordered with respect to the concepts of greater than and less than. Furthermore, it has the property of density: there are infinitely many rational numbers between any two different rational numbers. This makes it possible to carry out various measurements, for example, of the length of a line segment using a selected unit of measurement, to any degree of accuracy by means of rational numbers. Thus, the set of rational numbers turns out to be sufficient to satisfy many practical needs. The formal substantiation of the concepts of fraction and negative number was accomplished in the 19th century and, in contrast to the substantiation of the concept of natural number, posed no fundamental difficulties.

The set of rational numbers proved insufficient for the study of continuously changing variables, which necessitated a further extension of the concept of number, consisting in the transition from the set of rational numbers to the set of real numbers. This transition involved the addition to the rational numbers the irrational numbers. A discovery of vast fundamental importance was made by the ancient Greeks: not all precisely defined line segments (the term "precisely defined" itself is an idealization inherent in geometry) are commensurable; that is, the length of a line segment cannot always be expressed by rational numbers if an-

other line segment is taken as the unit. A classic example of incommensurable line segments is the side of a square and its diagonal. That incommensurable line segments exist was not an impediment to the development of geometry. The Greeks worked out a theory of the ratios of segments, presented in Euclid's *Elements*, that takes into account the possibility of incommensurability. The Greeks knew how to compare the magnitude of such ratios and to perform arithmetic operations on them (in purely geometrical form); that is, they treated them as numbers. However, they did not fully perceive the idea that the ratio of the lengths of incommensurable line segments may be considered as numbers. This may be attributed to the idealist separation of theoretical mathematics from practical problems prevalent in the school to which Euclid belonged. In Archimedes' works we find greater interest in practical problems, particularly approximate calculations of the ratios of incommensurable line segments, but even Archimedes did not develop the concept of irrational number as a number that expresses the ratio of the lengths of incommensurable line segments.

In the 17th century, the era of the birth of modern science, particularly modern mathematics, a number of methods of studying continuous processes and methods of approximate calculations were developed. A clear definition of the concept of real number is given by I. Newton, one of the founders of mathematical analysis, in *Arithmetica universalis*: "By number we mean not so much a set of units as the abstract ratio of some quantity to another quantity of the same kind that we have taken as unity." This formulation gives a unified definition of a real number, whether rational or irrational. Later, in the 1870's, the concept of real number was refined on the basis of a detailed analysis of the concept of continuity in the works of R. Dedekind, G. Cantor, and K. Weierstrass.

According to Dedekind, the property of continuity of a straight line consists in the fact that if all the points that make up a straight line are divided into two classes such that every point of the first class lies to the left of every point of the second class (that is, if the straight line is "broken" into two parts), then either the first class contains a rightmost point or the second class contains a leftmost point In either case, the "extreme" point is the point at which the "break" of the straight line occurred.

The set of all rational numbers does not possess the property of continuity. If the set of all rational numbers is divided into two classes such that every number of the first class is smaller than every number of the second, then upon such a subdivision (a Dedekind cut) it may turn out that there will be no largest number in the first class and no smallest number in the second. This will be the case, for example, if all negative rational numbers, zero, and all positive (rational) numbers whose square is less than 2 are placed in the first class and all positive (rational) numbers whose square is greater than 2 are placed in the second class. Such a cut is said to be irrational. Then the following definition of an irrational number is given: with every irrational cut in the set of rational numbers we associate an irrational number assumed to be larger than any number of the first class and smaller than any number of the second class. The set of all real numbers, both rational and irrational, already has the property of continuity.

Cantor's substantiation of the concept of real number differs from Dedekind's, although it too is based on an analysis of the concept of continuity. Both Dedekind's and Cantor's definitions use the abstraction of the actual infinite. For example, in Dedekind's theory an irrational number is defined by means of a cut in the set of all rational numbers, which is conceived as being given in its entirety.

Recent years have seen the development of the concept of computable numbers, that is, numbers approximations to which can be given by means of some algorithm. This concept is defined on the basis of a refined concept of algorithm and without resorting to the abstraction of the actual infinite.

The final stage in the development of the concept of number was the introduction of complex numbers (*see* COMPLEX NUMBERS). The concept of complex number emerged in the course of algebra's development. Apparently, it first arose among 16th-century Italian mathematicians (G. Cardano, R. Bombelli) in connection with the discovery of the algebraic solution of third- and fourth-degree equations. It is known that even the solution of a quadratic equation can sometimes lead to the operation of extracting the square root of a negative number, which cannot be performed in the domain of real numbers. This occurs only in cases when the equation does not have real roots. A practical problem that reduces to the solution of such a quadratic equation turns out to have no solution. The following fact was observed in connection with the discovery of the algebraic solution of third-degree equations. If all three roots of the equation are real numbers, then it proves necessary, in the course of calculations, to extract the square root of a negative number. The "imaginariness" that arises in this case disappears only if all subsequent operations are performed. This fact was the first stimulus to the study of complex numbers. However, mathematicians were slow to accept the use of complex numbers and operations performed on them. The remnants of disbelief in the legitimacy of complex numbers are reflected in the term "imaginary," preserved to this day. This disbelief was dissipated only after the establishment, in the late 18th century, of the geometrical interpretation of complex numbers as points in a plane and the establishment of the indisputable benefit derived from the introduction of complex numbers in the theory of algebraic equations, especially after the celebrated work of K. Gauss. Even before Gauss, in the works of L. Euler, complex numbers played a significant role not only in algebra but also in mathematical analysis. They acquired particular importance in the 19th century, in connection with the development of the theory of functions of a complex variable.

The set of all complex numbers, like the set of real numbers and the set of rational numbers, is closed with respect to the operations of addition, subtraction, multiplication, and division. Moreover, the set of all complex numbers has the property of algebraic closure, which means that every algebraic equation with complex coefficients has roots that are also in the domain of all complex numbers. The set of all real numbers, especially the rational numbers, does not have the property of algebraic closure. For example, the equation $x^2 + 1 = 0$, with real coefficients, does not have real roots. As established by Weierstrass, the set of all complex numbers cannot be enlarged by the inclusion of new numbers in such a way that all laws of operation that are valid in the set of complex numbers are preserved in the enlarged set.

In addition to the main line of development of the concept of number (natural numbers→rational numbers→real numbers→complex numbers), the specific requirements of certain branches of mathematics have engendered various generalizations of the concept of number in essentially different directions. For example, in branches of mathematics associated with set theory, the aforementioned concepts of cardinal and ordinal transfinite numbers are of major importance. *p*-adic numbers, systems of which are obtained from systems of rational numbers by the inclusion of new entities different from irrational numbers, have assumed major importance in modern number theory. Various systems of entities possessing properties that are more or less close to those of the set of integers or rational numbers—groups, rings, fields, and algebras (*see* GROUP; RING, ALGEBRAIC; and FIELD)—are being studied in algebra. (*See also* HYPERCOMPLEX NUMBERS.)

NUMBERS, THEORY OF, the science of the integers, or whole numbers. The concept of integer and the concept of arithmetical operations on numbers have been known since antiquity and are one of the first mathematical abstractions.

The natural numbers, that is, the positive integers, $1, 2, 3, \ldots$, the properties of natural numbers, and the operations on such numbers occupy a special place among the integers, that is, the numbers $\ldots, -3, -2, -1, 0, 1, 2, 3, \ldots$. All natural numbers greater than unity fall into one of two classes; the first class includes numbers that have exactly two natural divisors, namely unity and themselves, while the second class includes all other

numbers. The numbers of the first class have come to be called prime numbers, and the numbers of the second class, composite numbers. The properties of prime numbers and their relationship to all natural numbers were studied by Euclid (third century B.C.). If the prime numbers are written in sequence, it can be seen that their relative density decreases: there are four prime numbers, or 40 percent, in the first ten numbers; 25, or 25 percent, in the first hundred; 168, or about 17 percent, in the first thousand; 78,498, or about 8 percent, in the first million, and so forth; however, there are infinitely many prime numbers (Euclid).

The prime numbers include some pairs the difference between whose members is equal to two (twin primes), but whether such pairs are infinite or finite in number has not been proved.

Euclid believed it obvious that all the natural numbers could be obtained by multiplying only prime numbers and that every natural number could be represented uniquely (to within the order of the factors) as the product of prime numbers. Thus, the prime numbers form the multiplicative foundation of the natural numbers. The first problems of prime numbers were concerned with how frequently primes occur in the natural sequence and how far they are from each other. The study of the distribution of prime numbers led to the creation of an algorithm (rule) that makes it possible to compile tables of primes. The sieve of Eratosthenes (third century B.C.) is such an algorithm. In *Elements*, Euclid indicated a method of finding the greatest common divisor of the two numbers (Euclid's algorithm), a consequence of which is the theorem of the unique factorization of the natural numbers into prime factors.

The problem of integral solutions of different types of equations also dates to antiquity. The simplest equation in integral values of the unknowns is the linear equation

$$aX + bY = c$$

where a, b, and c are pairwise relatively prime integers. The solution of the equation $aX + bY = 1$ is found by using Euclid's algorithm, from the solution of which all solutions of the original equation are then obtained. Another equation in integral values of the unknowns is $X^2 + Y^2 = Z^2$ (the solutions $X = 3$, $Y = 4$, $Z = 5$ are Pythagorean numbers), all of whose solutions in integers were given in *Elements* (Book X, Proposition 29):

$$X = r^2 - q^2 \qquad Y = 2rq \qquad Z = r^2 + q^2$$

where r and q are integers. Euclid was also familiar with the equation $aX^2 + 1 = Y^2$, which subsequently became known as Pell's equation (*see* PELL'S EQUATION). In *Elements* (Book X, Proposition 9), Euclid provided all the solutions of this equation, beginning with the smallest solution, for the case $a = 2$. A systematic exposition of the theory of equations in integral values of the unknowns known at the time was given by Diophantus in *Arithmetica* (mid-third century B.C.). This book played a major role in the subsequent development of the branch of number theory concerned with the solution of equations in integral values of the unknowns that are now called Diophantine equations (*see* DIOPHANTINE EQUATIONS).

The next stage in the development of number theory is linked with P. de Fermat, who contributed a number of outstanding discoveries in the theory of Diophantine equations and the theory of the divisibility of integers. Fermet advanced the hypothesis now called Fermat's last theorem and proved the theorem known as Fermat's theorem, which plays an important role in the theory of congruences and its most recent generalizations (*see* CONGRUENCE). Continuing Fermat's studies of the theory of the divisibility of numbers, L. Euler proved a theorem that generalizes Fermat's theorem. He also contributed the first proofs of Fermat's last theorem for the exponent $n = 3$.

By the turn of the 18th century, the science of integers had amassed many facts that made it possible to construct orderly theories and general methods of solving various problems of number theory.

Euler was the first mathematician to create general methods and to apply other branches of mathematics, particularly mathematical analysis, to the solution of problems of number theory. While investigating the problem of the number of nonnegative, integral solutions $X_1, \ldots, X_n$ of linear equations of the type

$$a_1X_1 + \cdots + a_nX_n = N$$

where $a_1, \ldots, a_n$ are natural numbers, Euler constructed the generating function $\Phi(z)$ in the variable z such that the coefficients of its expansion in a power series in z are equal to the number of solutions, for different values of N, of the indicated equation. The function $\Phi(z)$ is defined as the formal product $\Phi(z) = \Phi_1(z) \cdot \ldots \cdot \Phi_n(z)$ of the series

$$\Phi_1(z) = \sum_{k=0}^{\infty} z^{a_1k}, \ldots, \Phi_n(z) = \sum_{k=0}^{\infty} z^{a_nk}$$

each of which converges when $|z| < 1$ and has a rather simple form, being the sum of the terms of an infinite geometric progression:

$$\Phi_1(z) = \frac{1}{1 - z^{a_1}}, \ldots, \Phi_n(z) = \frac{1}{1 - z^{a_n}}$$

Consequently,

$$\Phi(z) = \frac{1}{(1 - z^{a_1}) \ldots (1 - z^{a_n})} = \sum_{N=0}^{\infty} I(N)z^N$$

where $I(N)$ is the number of solutions of the equation being studied. Euler's method of generating functions was the source for the Hardy and Littlewood circle method, a far-reaching development of which was I. M. Vinogradov's method of trigonometric sums.

Another problem of number theory that stimulated the creation of a powerful method was the problem of prime numbers. In proving Euclid's theorem that the number of prime numbers is infinite, Euler considered the product over all prime numbers p

$$\prod_p \left(1 - \frac{1}{p^s}\right)^{-1} = \prod_p \left(1 + \frac{1}{p^s} + \frac{1}{p^{2s}} + \cdots\right)$$

for $s > 1$. This product converges, and if it is expanded, by virtue of the unique factorization of the natural numbers into prime factors, it turns out that this product is equal to the sum of the series

$$\sum_{n=1}^{\infty} \frac{1}{n^s}$$

whence Euler's identity follows:

$$\prod_p \left(1 - \frac{1}{p^s}\right)^{-1} = \sum_{n=1}^{\infty} \frac{1}{n^s} \qquad s > 1$$

When $s = 1$ the series on the right diverges (a harmonic series), and consequently Euclid's theorem follows from Euler's identity. Euler's idea thus became the basis for the modern theories of the zeta function (*see* ZETA FUNCTION). Euler and C. Goldbach contributed the first formulations of additive problems, that is, problems connected with addition, involving prime numbers.

By the mid-19th century, the theory of numbers was basically constructed through the efforts of K. Gauss, J. Lagrange, A. Legendre, P. Dirichlet, P. L. Chebyshev, J. Liouville, and E. Kummer.

Gauss created the theory of congruences, also known as the arithmetic of residue classes, which was used to prove the theorem that a prime number is the sum of two squares if and only if it has the form $4n + 1$, and the theorem of the representability of every natural number as the sum of four squares of integers. Furthermore, the theory of congruences led to the important number-theoretic concepts of character and trigonometric sum (*see* CHARACTER). The Legendre symbol is the simplest character (*see* LEGENDRE SYMBOL).

Gauss studied the properties of quadratic residues and nonresidues (*see* QUADRATIC RESIDUE). The fundamental theorem in this area is the quadratic reciprocity law, in proving which Gauss considered finite sums of the type

$$S(a) = \sum_{n=1}^{p} e^{2\pi i an^2/p} \qquad 0 < a \leq p - 1$$

where a is an integer. Sums of this $n = 1$ type and their generalizations have come to be called trigonometric sums, since by virtue of Euler's formula $e^{i\phi} = \cos \phi + i \sin \phi$ they can be represented as the sum of sines and cosines.

Gauss, and later Dirichlet, continuing Euler's studies, created

the theory of quadratic forms, in other words, the theory of the representation of natural numbers by forms of the type $ax^2 + 2bxy + cy^2$, where a, b, and c are integers.

Gauss and Dirichlet were the first to consider the problem of the number of lattice points in regions on a plane. Gauss proved that the number of lattice points in the circle $X^2 + Y^2 \leq R^2$ is equal to $\pi R^2 + O(R)$, and Dirichlet in turn proved that the number of lattice points with positive coordinates under the hyperbola $xy = N$ is equal to $N(\ln N + 2C - 1) + O(\sqrt{N})$, where C is Euler's constant. Generalizations of these two propositions and the finding of optimal remainders in the formulas written above (Gauss' problem of lattice points in a circle and Dirichlet's problem of divisors) were the source for a major chapter in number theory.

Theorems on the infinite number of prime numbers in arithmetic progressions of the type $4k \pm 1$ and $6k \pm 1$ had long been known, but Dirichlet was the first to prove the general theorem that there is an infinite number of primes in progressions of the type

$$nk + l \qquad n = 0, 1, 2, \cdots$$

where k (the difference of the progression) and l (its first term) are relatively prime. Dirichlet considered the following analogue of Euler's product over all primes:

$$\prod_p \left(1 - \frac{\chi(p)}{p^s}\right)^{-1}$$

Here $\chi(p)$ is not equal to zero and is periodic $\chi(n + k) = \chi(n)$ with a period k and completely multiplicative, that is, $\chi(nm) = \chi(n)\chi(m)$ for any integral n and m. This function is called a Dirichlet character. Dirichlet characters can be used to "cut out" an arithmetic progression. For every natural k there are $\phi(k)$ Dirichlet characters [$\phi(k)$ is Euler's ϕ-function]. If the sum of the numbers $\chi(n)$ over all possible characters corresponding to k is considered, it will be equal to $\phi(k)$ if n upon division by k gives a remainder of 1; otherwise it is equal to 0. If $s > 1$, an analogue of Euler's identity is obtained:

$$\prod_p \left(1 - \frac{\chi(p)}{p^s}\right)^{-1} = \sum_{n=1}^{\infty} \frac{\chi(n)}{n^s}$$

where the series on the right is a Dirichlet series (*see* DIRICHLET SERIES). By studying the behavior of such series as $s \to 1 + 0$, Dirichlet proved his theorem of the infinite number of prime numbers in an arithmetic progression.

Dirichlet characters are of considerable importance in both number theory itself and other branches of mathematics, such as algebra and topology, while Dirichlet series constitute a major branch of the modern theory of functions.

A new approach to the problem of the distribution of prime numbers was proposed by Chebyshev. Let $\pi(X)$ be the number of prime numbers that do not exceed X. Euclid's theorem asserts that $\pi(X) \to +\infty$ as $X \to +\infty$. Chebyshev proved the more exact result that

$$a \frac{X}{\ln X} < \pi(X) < b \frac{X}{\ln X}$$

where $a > \frac{1}{2} \ln 2$ and $b < 2 \ln 2$, and that if

$$\frac{\pi(X) \ln X}{X}$$

tends to a limit as $X \to \infty$, then this limit is equal to 1. Chebyshev also made another discovery in the theory of prime numbers. It had been noted in calculations that a prime number lies in the interval $(X, 2X)$, $X \geq 2$, a hypothesis known as Bertrand's postulate. Chebyshev proved Bertrand's hypothesis in 1852 but obtained a more exact result by decreasing the length of the interval considered. Thus, together with the problem of twin primes, that is, the problem of the least difference $p_{n+1} - p_n$, the problem of finding upper bounds for this difference arose and began to be solved.

The study of indeterminate equations and, first and foremost, of Fermat's equation led to the creation of a new branch of number theory—the theory of algebraic numbers. Attempting to prove Fermat's last theorem, Kummer arrived at the equation

$$x^n = z^n - y^n = \prod_{i=1}^{n} (z - \alpha_i y)$$

where the α_i are the nth roots of unity. Considering numbers of the type $z + \alpha_i y$, where z and y are integers, as "new integers," Kummer constructed the arithmetic of integers of the algebraic number field generated by α_i, that is, the set of numbers that is obtained from α_i by applying all four arithmetical operations to it. If the theorem of the unique factorization of integers into prime factors were valid in such a field, then the above equation would yield a contradiction. However, this is not always the case. In order to preserve the validity of the theorem, Kummer introduced ideal factors. A number of problems arose the solution of which led to the theory of algebraic numbers, with its many new concepts and results.

A new branch in number theory—the study of the arithmetic of the number line—emerged with the study of the properties of integers. Euler had already noted that the square roots of integers and the logarithms of integers fundamentally differ from one another. This fact was given an exact mathematical formulation after the work of Liouville (1844), who introduced the concepts of algebraic number and transcendental number (*see* ALGEBRAIC NUMBER and TRANSCENDENTAL NUMBER). It turns out that algebraic numbers are approximated "poorly" by rational fractions. Liouville proved that if an algebraic number is a root of an equation of degree n, then it is impossible to approximate it substantially closer than to within Q^{-n} by fractions of the type P/Q, where P and Q are relatively prime integers (Liouville's theorem). From here directly follows the existence of an infinite number of nonalgebraic numbers, which came to be called transcendental numbers. For example, the number

$$\sum_{n=1}^{\infty} 2^{-n!}$$

will be such a number. However, the question of whether specific numbers are algebraic or transcendental is difficult, and the classical constants π and e were the first to be so examined. Number theory continued to develop in many directions in the late 19th and early 20th centuries. General methods applicable to a broad range of problems, sometimes quite far removed from the original problems, were devised to solve individual problems. The methods and concepts developed often stimulated the development of new fields.

Two trends emerged in the theory of algebraic numbers: the study of specific numbers with a view to proving their transcendentality, and the study of the degree of approximation of algebraic numbers by rational or algebraic numbers. In the first trend, general methods were devised by C. Hermite (1873), who proved the transcendentality of the number e, and by the German mathematician C. L. F. von Lindemann, who proved the transcendentality of the number π and thus solved the problem of squaring the circle. In the second trend, A. Thue proposed (1909) a method of proving that in Liouville's inequality an algebraic number cannot be approached substantially closer than to within $Q^{-n/2}$. A consequence of this was Thue's theorem on the finiteness of the number of solutions in integers x and y of the equation

$$a_0 x^n + a_1 x^{n-1} y + \cdots + a_{n-1} x y^{n-1} + a_n y^n = A$$

where $a_0, a_1, \ldots, a_n$ and A are integers and $n \geq 3$.

The further study of prime numbers led to a new method in number theory connected with the function $\zeta(s)$. B. Riemann proved that the zeta function $\zeta(s)$ can be continued analytically to the entire complex plane, is analytic at every point of the plane except $s = 1$, where it has a pole of order 1 with a residue of 1, and satisfies the functional equation $\xi(s) = \xi(1 - s)$ with

$$\xi(s) = \frac{1}{2} s(s - 1)\pi^{-s/2}\Gamma\left(\frac{s}{2}\right)\zeta(s)$$

and $\Gamma(s)$ the gamma function. The zeta function has infinitely many zeros in the strip $0 \leq \operatorname{Re} s \leq 1$ (these zeros are said to be nontrivial, and the strip is called the critical strip). Riemann es-

tablished the close relationship between the nontrivial zeros of $\zeta(s)$ and the asymptotic behavior of $\pi(x)$. The study of the asymptotic formula for Chebyshev's function

$$\psi(x) = \sum_{n \le x} \Lambda(n)$$

where $\Lambda(n) = \ln p$ if $n = p^k$ and $\Lambda(n) = 0$ if $n \neq p^k$, is equivalent to the same problem for the function $\pi(x)$. The function $\psi(x)$ can be expressed in terms of the integral of the generating function $\zeta'(s)/\zeta(s)$:

$$\psi(x) = \frac{1}{2\pi_i} \int_{2-i\infty}^{2+i\infty} \left(-\frac{\zeta'(s)}{\zeta(s)} \right) \frac{x^s}{s}\, ds$$

Riemann advanced the hypothesis that all nontrivial zeros of $\zeta(s)$ lie on the line $\operatorname{Re} s = \frac{1}{2}$, from which it follows that

$$\psi(x) = x + O(\sqrt{x} \ln^2 x)$$

$$\pi(x) = \int_2^x \frac{du}{\ln u} + O(\sqrt{x} \ln x)$$

The Riemann hypothesis follows from the validity of any one of the last two equations. Dirichlet's L series were studied in a similar manner. In 1896, C. de La Vallée Poussin and J. Hadamard proved that $\zeta(s) \neq 0$ in the region $\operatorname{Re} s \geq 1$, whence followed the formula (the asymptotic law of the distribution of prime numbers)

$$\pi(x) \sim \frac{x}{\ln x}$$

Furthermore, La Vallée Poussin proved that $\zeta(s) \neq 0$ in the region

$$\operatorname{Re} s \geq 1 - \frac{c}{\ln(|t| + 2)}$$

and that

$$\pi(x) = \int_2^x \frac{du}{\ln u} + O(xe^{-c_1\sqrt{\ln x}})$$

where c and c_1 are positive constants. He also obtained the same result for prime numbers in arithmetic progressions: if $\pi(x, k, l)$ is the number of primes of the type $kn + l$, $n \leq x$, and k and l are relatively prime, then

$$\pi(x, k, l) = \frac{1}{\phi(k)} \int_2^x \frac{du}{\ln u} + O(xe^{-c_1\sqrt{\ln x}})$$

The method of obtaining asymptotic formulas for $\pi(x)$, $\psi(x)$, and $\pi(x, k, l)$, which is called the complex integration method, has found numerous applications. The basis of this method is the formula

$$\frac{1}{2\pi i} \int_{b-i\infty}^{b+i\infty} \frac{X^s}{s}\, ds = \begin{cases} 1 & \text{if } 0 < X < 1 \\ 0 & \text{if } X > 1 \end{cases}$$

The theory of quadratic forms, originated by Euler, Gauss, and Dirichlet, was further developed by A. N. Korkin, E. I. Zolotarev, and A. A. Markov. In particular, Korkin and Zolotarev proved the theorem that the variables of any positive quaternary quadratic form with determinant D can be assigned integral values such that the value of the form will not exceed $\sqrt[4]{4D}$, and there exist forms whose minima are equal to $\sqrt[4]{4D}$. The following is an example of such a form:

$$\sqrt[4]{4D}\,(x_1^2 + x_2^2 + x_3^2 + x_4^2 + x_1x_2 + x_1x_3 + x_1x_4)$$

Markov's research dealt with the minima of binary quadratic forms with positive determinant and led to a number of new discoveries.

The problems of lattice points in regions on a plane were developed further in the work of G. F. Voronoi, who devised (1903) a method to prove that the remainder term in Dirichlet's asymptotic formula for the number of lattice points under a hyperbola is of the order of the cube root of the main term. Later (1966), W. Sierpinski applied Voronoi's method to Gauss' problem of lattice points in a circle, with the same result. At the same time, attempts were undertaken to find solutions of the additive problems of number theory, particularly the Waring problem, solved by D. Hilbert in 1909 (*see* WARING PROBLEM).

The second, third, and fourth decades of the 20th century were exceptionally rich in new ideas and methods in number theory. H. Weyl, in solving problems connected with the stability of the solar system, arrived at the concept of the uniform distribution of the fractional parts of functions on the integers: the fractional parts of the real-valued function $F(x)$ are said to be distributed uniformly over $[0, 1)$ for $x = 1, 2, 3, \ldots$ if the number of times the fractional parts of $F(x)$ occur in any interval of $[0, 1)$ is proportional to the length of the interval. Weyl proved that for a uniform distribution of the fractional parts of $F(x)$, it is necessary and sufficient that the following equation be fulfilled for any fixed $|m| > 0$:

$$S(F) = \sum_{0 < x \le p} e^{2\pi i m F(x)} = o(P)$$

He obtained nontrivial estimates of $|S(F)|$ in the case where $F(x)$ is a polynomial whose leading coefficient is an irrational number. Vinogradov, studying the distribution of the values of the Legendre symbol on segments of short length compared with the modulus, proved (1914) the inequality

$$\left| \sum_{n \le x} \left(\frac{n + a}{p} \right) \right| < \sqrt{p} \ln p \qquad X > 0$$

from which it follows that the numbers of quadratic residues and nonresidues on any segment whose length is slightly greater than $\sqrt{p} \ln p$ are asymptotically equal. Furthermore, he advanced the hypothesis that this would be true when $X > p^{\epsilon}$, where $\epsilon > 0$ is an arbitrarily small number. In 1917, Vinogradov proved that the number of lattice points in the region $0 < y \leq f(x)$, $a < x \leq b$, under certain restrictions on the order of growth of the second derivative of $f(x)$, is equal to the area of this region to within a term of the order of the cube root of the main term. The Czech mathematician V. Jarník later established that under the assumptions made with respect to $f(x)$, the accuracy of this formula cannot be improved significantly.

The Norwegian mathematician V. Brun proved (1919) a number of theorems that in a sense approached the problem of twin primes and Euler's problem. Specifically, he proved the infiniteness of the number of pairs u_1 and u_2 such that $u_2 - u_1 = 2$ and such that the number of prime divisors u_1 and u_2 does not exceed nine; he also proved the solvability of the equation $u_1 + u_2 = 2N$, under the same conditions on u_1 and u_2.

G. Hardy and J. Littlewood published (1922–23) a series of monographs under the general title *Partitio numerorum*, in which they developed a general method of solving additive problems of number theory, which subsequently came to be called the circle method. This method, using the Waring problem as an example, consists in the following. Let

$$\Phi(z) = \sum_{x=0}^{\infty} z^{x^n} \qquad |z| < 1$$

then,

$$\Phi^k(z) = \sum_{N=1}^{\infty} I_k(N) z^N$$

Here $I_k(N)$ is the number of solutions of Waring's equation and is given by

$$I_k(N) = \frac{1}{2\pi i} \int_{|z| \le R < 1} z^{-N-1} \Phi^k(z)\, dz$$

Hardy and Littlewood studied the last integral as $R \to 1 - 0$. The circle of integration is broken in a specific way into "major" and "minor" arcs (hence the method's name). Here, the integrals over "major" arcs give the main term of the asymptotic formula for $I_k(N)$, and the integrals over the "minor" arcs give the remainder term. The result is the asymptotic formula

$$I_k(N) = \sigma(N) \frac{\Gamma(1 + 1/n)^k}{\Gamma(k/n)} N^{k/n-1} + O(N^{k/n-1-\delta})$$

where $\sigma(N)$ is a certain "singular series," $\sigma(N) \geq c > 0$, $\delta > 0$, and $k \geq (n-2)2^{n-1} + 5$. Using this method, Hardy and Littlewood obtained several results. They obtained a new solution of the Waring problem, a solution in a form more exact than Hilbert's solution. They also obtained a conditional solution of the Goldbach problem and formulated and wrote out hypothetical formulas for the number of solutions of a large number of equations with prime numbers.

In the early 1930's, Vinogradov developed the method of trigonometric sums, which made it possible to solve many problems in number theory. For example, working on the Waring problem, Vinogradov observed (1929) that the Hardy and Littlewood result would be much simpler if trigonometric sums of the type

$$\sum_{0<x\leq p} e^{2\pi i F(x)}$$

where $F(x)$ is a real function, were considered instead of generating functions and if the following relation were used:

$$\int_0^1 e^{2\pi i \alpha m}\, d\alpha = \begin{cases} 1 & m = 0 \\ 0 & m \neq 0 \end{cases}$$

where m is an integer. Then, $I_k(N)$ in the Waring problem will be written as

$$I_k(N) = \int_0^1 S^k(\alpha) e^{-2\pi i \alpha N}\, d\alpha$$

where

$$S(\alpha) = \sum_{0<x<N^{1/n}} e^{2\pi i \alpha x^n}$$

Then, the integration interval [0, 1] is divided by rational irreducible fractions of the type a/b, $0 \leq a < b \leq \tau$, where τ is a parameter that depends on N, into subintervals similar to the "major" and "minor" arcs of the circle method. Intervals corresponding to fractions with small denominators and the sum of the integrals over them give the main term of the asymptotic formula for $I_k(N)$. Other intervals correspond to minor arcs; for them, Vinogradov estimated $|S(\alpha)|$ by Weyl's method and obtained the remainder term. Other problems of number theory also reduce to trigonometric sums, such as the problem of the distribution of fractional parts of functions, the problem of lattice points in regions on a plane and in space, and the problem of the order of growth of the zeta function in the critical strip. What is important in such problems is whether a more exact evaluation of the modulus of a trigonometric sum is possible.

Vinogradov proposed two methods of estimating trigonometric sums. The first method (1934) made it possible to obtain new estimates of Weyl sums, and the current estimates were obtained by way of this method. In addition, an asymptotic formula was derived in the Waring problem for $k \geq 4n^2 \ln n$, and it was proved that no more than $3n \ln n + 11n$ terms suffice for Waring's equation to be solvable when $N \geq N_0(n)$. A new remainder term was also obtained in the asymptotic formulas for $\pi(x)$ and $\psi(x)$ (Vinogradov, 1957) of order

$$O(xe^{-c(\ln x)^{0.6}}) \qquad c > 0$$

and the Hilbert-Kamke problem was solved (K. K. Mardzhanishvili, 1953).

Vinogradov's second method (1937) made it possible to evaluate trigonometric sums in which summation is carried out over prime numbers:

$$T = \sum_{p\leq N} e^{2\pi i \alpha p}$$

This led to the proof of the asymptotic formula for the number of representations of an odd number by the sum of three primes, from which it followed that all sufficiently large odd numbers are the sum of three primes. The Goldbach problem was thus solved (*see* GOLDBACH PROBLEM). Vinogradov's second method also led to the solution of other general problems of number theory, such as the Waring problem in prime numbers and the problem of the distribution of quadratic residues and nonresidues in sequences of the type $p + a$, where p assumes prime values.

The development of Thue's ideas (construction of an auxiliary polynomial with a root of high multiplicity) and G. Pólya's ideas (United States; an entire analytic function that assumes integral values at positive lattice points and that grows more slowly than $2^{\gamma|S|}$, $\gamma < 1$, is a polynomial) led A. O. Gel'fond and the German mathematician T. Schneider (1934) to the solution of Hilbert's seventh problem, which asserts the transcendentality of numbers of the type α^β, where $\alpha \neq 0, 1$ and β is an algebraic number of degree ≥ 2. K. Siegel proved a series of theorems on the transcendentality of the values of functions of the type e^x (E functions) at algebraic points.

In algebraic number theory, a number of theorems that generalize theorems of the theory of integers to the integers of algebraic number fields have been proved; some of them have also led to purely arithmetic results, including the theory of the representation of numbers by complete and incomplete decomposable forms (Pell's equation is the simplest of these problems). The theory of solutions of congruences of two or more variables has also been developed. It follows, for example, from this theory that the congruence

$$F(x, y) \equiv 0 \pmod{p}$$

where F is an absolutely irreducible polynomial, has $p + O(\sqrt{p})$ solutions (the Hasse-Weyl theorem).

Between the late 1940's and the present (1978), many papers have appeared in number theory in quite varied areas. Research is being conducted in classical number theory and in various new branches of number theory. The Soviet mathematicians B. N. Delone and D. K. Faddeev investigated in detail (1940) the Diophantine equation $x^3 - ay^3 = 1$. In the theory of the Riemann zeta function, A. Selberg (Norway, 1942) proved that a nonzero fraction of all zeros of $\zeta(s)$ lies on the critical line $\operatorname{Re} s = \frac{1}{2}$. Iu. V. Linnik proved that the smallest prime number in an arithmetic progression with a difference k does not exceed k^c, where c is a constant, and worked out the dispersion method (1958–61), which he used to derive the asymptotic formula for the number of representations of a natural number N by the sum of a prime number and two squares (the Hardy-Littlewood problem). Linnik also used this method to obtain an asymptotic formula for the number of solutions of an indeterminate equation of the type $p - a = xy$, where $p \leq N$, $xy \leq N$, and a is a fixed integer (Titchmarsh's problem of prime divisors). Vinogradov's method of trigonometric sums was developed further by Vinogradov himself and by his students. Unsuccessful attempts to prove Riemann's hypothesis led to a number of methods that obviate it and at the same time make it possible to solve certain problems of number theory that are derived from the hypothesis. These include the problem of estimating the difference $p_{n+1} - p_n = \Delta_n$, which reduces to estimating the number of zeros of the zeta function in rectangles of the type $\sigma \lesssim \operatorname{Re} s \leq 1$, $\sigma > \frac{1}{2}$, and $|\operatorname{Im} s| \leq T$. It follows from such "density" theorems and the bound on the zeros of $\zeta(s)$ obtained on the basis of Vinogradov's method that $p_{n+1} - p_n = O(p_n^{0.6})$. Similar results have also been obtained in the theory of the distribution of prime numbers in arithmetic progressions and in its application to additive problems involving prime numbers.

In the theory of transcendental numbers, the British mathematician K. Roth strengthened (1955) Thue's method and proved that an algebraic number cannot be approximated by a rational fraction P/Q much more accurately than to within $Q^{-2-\epsilon}$, where $\epsilon > 0$ is arbitrarily small; the British mathematician A. Baker obtained (1966) an estimate from below for a linear form of the logarithms of algebraic numbers. This led to an effective proof of Thue's theorem of the finiteness of the number of solutions of the equation

$$a_0x^n + a_1x^{n-1}y + \cdots + a_{n-1}xy^{n-1} + a_ny^n = A$$

(bounds on these solutions are given) and to an effective strengthening of Liouville's theorem of the approximation of algebraic numbers by rational fractions. A large number of problems of number theory have yet to be solved, including the problems of twin primes, the infiniteness of prime numbers of the type $n^2 + 1$, lattice points in a circle and under a hyperbola, the distribution of the zeros of the zeta function, and the transcendentality of the numbers $\pi + e$ and Euler's constant.

NUMERAL, a nominal, the general lexical meaning of which is a quantity of persons or things. Grammatically, numerals are marked for the category of case (in languages with a developed morphology) and for gender (in languages with grammatical gender, some numerals possess marked forms; for example, Russian *dva*, "two" [masculine and neuter], and *dve*, "two" [feminine]) and are not marked for the category of number.

In Russian, numerals may be definite (*dva*, "two," *desiat'*, "ten") or indefinite (*mnogo*, "many," *malo*, "few"), depending on the nature of the quantitative expression. Collective numerals designate quantity as a group (*dvoe*, "two," *troe*, "three," *piatero*, "five," *oba*, "both"); they constitute a special group. The structure of Russian numerals may be simple (*dva*, "two," *tri*, "three," *odinnadtsat'*, "eleven"), compound (*piat'desiat*, "fifty," *sem'desiat*, "seventy"), or complex (*tridtsat' shest'*, "thirty-six," *sto desiat'*, "one hundred ten"). Many scholars consider ordinals and the word *odin* ("one") as adjectives; such words have forms marked for both number and grammatical gender. The words *desiatok* ("a group of ten"), *sotnia* ("a group of one hundred"), and *tysiacha* ("[a group of] one thousand") are nouns, inasmuch as they have all the formal characteristics of a noun. In the development of the Slavic languages, some numerals originated from other parts of speech; for example, Russian *piat'* ("five") was classified as a noun. Numerals should be distinguished from other words with quantitative meaning.

V. A. VINOGRADOV [29–629–3]

NUMERICAL METHODS, in mathematics, methods of approximate solution of mathematical problems through the performance of a finite number of elementary operations on numbers.

The elementary operations used are arithmetic operations, generally carried out approximately, and subsidiary operations, such as recording intermediate results and extracting information from tables. Numbers are expressed by a limited set of digits in some positional numeration system, for example, the decimal or binary system. The number line is thus replaced by a discrete system of numbers, sometimes called a net. A function of a continuous variable accordingly is replaced by a table of the function's values in this discrete system of numbers (*see* MATHEMATICAL TABLE). Operations of analysis that act on continuous functions are replaced by algebraic operations on the function's values in the table. Numerical methods reduce the solution of mathematical problems to computations that can be performed manually or by means of calculating machines. The development of new numerical methods and their use in computers have led to the rise of computer mathematics. [29–629–1]

NUMERICAL SOLUTION OF EQUATIONS, the process of finding approximate solutions of algebraic and transcendental equations. The numerical solution of equations reduces to performing arithmetic operations on the coefficients of equations and on the values of their constituent functions; the process makes it possible to find solutions of equations to any predefined accuracy. Many problems of mathematics and its applications reduce to the numerical solution of equations.

Although I. Newton (17th century) was the first to develop a general method of numerical solution of equations, in the early 13th century L. Fibonacci calculated a root of the equation $x^3 + 2x^2 + 10x = 20$ with an error of less than $\frac{1}{3} \times 10^{-10}$. In the late 16th century J. Bürgi of Switzerland calculated a root of the equation $9 - 30x^2 + 27x^4 - 9x^6 + x^8 = 0$, which defines the length of a side of a regular nonagon. At approximately the same time F. Vieta gave a method of calculating roots of algebraic equations that was similar to Newton's method.

The numerical solution of an algebraic equation may be divided into the following stages: (1) identification of multiple roots, which reduces the problem to solving an equation with simple roots; (2) determination of boundaries between which roots of the equation may lie; (3) isolation of roots, that is, the determination of intervals such that each contains no more than one simple root (*see* STURM'S THEOREM); (4) rough determination of the approximate value of a root, which is performed graphically or by some other method—for example, by studying the changes in sign of the left-hand side of the equation; (5) calculation of the root to the specified accuracy. Among the most widely used methods for the numerical solution of algebraic equations are the method of false position, Newton's method, Lobachevskii's method, the method of successive approximations, and expansion in series.

The numerical solution of transcendental equations is limited to stages (4) and (5). The numerical solution of differential equations is discussed in APPROXIMATE SOLUTION OF DIFFERENTIAL EQUATIONS.

NUX VOMICA (*Strychnos nux-vomica*), also strychnine tree a small tree (to 15 m high) of the family Loganiaceae. The leaves are opposite, leathery, and shiny. The small greenish white flowers are gathered into umbellate cymose inflorescences. The fruit is a berry, with two to eight very hard disk-shaped seeds with shiny, silky hairs.

The nux vomica is native to the tropical forests of Asia and northern Australia; it is cultivated in the tropics of Africa. Like several other closely related species, it contains poisonous alkaloids (strychnine, brucine), mainly in the seeds. Strychnine (nitrate) and galenicals (the dried extract and tincture of nux vomica) are used in medicine and veterinary medicine as tonics to treat lowered metabolism, rapid fatigability, hypotension, weakened cardiac activity (resulting from intoxication and infection), pareses and paralyses, and atony of the stomach. The genus *Strychnos* contains 150 to 200 species, which are common to the tropics of both hemispheres. Some species are used as a source of the arrow poison curare, which contains alkaloids called curarines; others are used to treat snakebites and to purify drinking water. [29–592–1]

OCCUPATION NUMBER, in quantum mechanics and quantum statistics, a number that indicates the extent to which quantum states are filled by the particles of a quantum-mechanical system consisting of many identical particles. For a system consisting of fermions, or particles with half-integral spin, the occupation numbers may take only two values: 0 for empty states or 1 for filled states. For a system consisting of bosons, or particles with integral spin, the occupation numbers may take any nonnegative integral values: 0, 1, 2, . . . For a given system, the sum of all occupation numbers should be equal to the number of particles in the system.

Occupation numbers may also be used to describe the numbers of elementary excitations, or quasiparticles, of quantum fields. In this case, the sum of the occupation numbers is not fixed.

The occupation numbers averaged over a state in statistical

equilibrium for ideal quantum gases are specified by either the Fermi-Dirac or the Bose-Einstein distribution function [*see* equation (19) in STATISTICAL MECHANICS]. The concept of occupation numbers underlies the method of second quantization, which is also called the occupation-number representation.

D. N. ZUBAREV [29–628–1]

OEDIPUS, in ancient Greek mythology, a king of Thebes.

In Sophocles' tragedy *Oedipus Tyrannus* (c. 425 B.C.), Oedipus' father, Laius, having received an oracle that he would be slain by his son, orders his wife Jocasta to abandon their new-born baby on Mount Cithaeron. The infant is saved by shepherds and is brought to Polybus, king of Corinth, who raises him as his own son. Upon reaching manhood, Oedipus is told by the Delphic oracle that he will slay his father and wed his mother. Afraid to return to Corinth, which he considers his homeland, Oedipus sets out on the road. While on the road he quarrels with and kills an unknown nobleman, who in fact is Laius. Subsequently, Oedipus solves the riddle of the Sphinx and frees Thebes; in return he is proclaimed king of Thebes and marries the widowed Jocasta. For 20 years he lives in happiness, unsuspecting that the prophecy of the Delphic oracle has come true. When a plague breaks out in Thebes and the Delphic oracle prophesizes that only the banishment of Laius' murderer will save the city, Oedipus learns of his crimes. In despair, he puts his eyes out with a clasp from the dress of Jocasta, who has hanged herself, and goes into exile, accompanied by his loyal daughter Antigone. Oedipus dies in Colonus, a suburb of Athens.

Versions of the myth appeared in the works of classical authors, including Euripides and Seneca, and in literature and music beginning with the Renaissance, for instance, in the works of P. Corneille, J. Cocteau, T. S. Eliot, and I. F. Stravinsky.

[29–1685–2]

OEDOGONIALES, an order or class of green algae that resemble branching or nonbranching filaments. The cells are uninucleate with parietal dissection or reticular chloroplast. The outer layer of the membrane contains chitin. The membranes of some cells have narrow zonules in the form of truncated cones; the zonules are traces of the tearing of the outer layer of the membrane during cell division. Reproduction is asexual (large zoospores equipped in front with a crown of flagella form singly in the cell) or sexual (oogamy). In some Oedogoniales the spermatozoids are formed in pairs in special disk-like cells. In others, disk-like cells produce small zoospores that germinate on or near oogoniums into dwarf male plantlets.

Oedogoniales are found widely in fresh waters, especially in warm and sluggish reservoirs. There are 470 species, making up three genera. About 100 species occur in the USSR. [29–1688–3]

OIL CAKE, a by-product of oil extraction obtained after the fat is extracted from the seeds of oil plants by organic solvents. Various types of oil cake (peanut, mustard, castor bean, hemp, corn) are distinguished according to the raw material from which they come. Oil cake is a valuable protein feed. One hundred kilograms of sunflower oil cake contains about 100 feed units and 37.6 kg of digestible protein; 100 kg of hemp oil cake contains 82 feed units and 24.8 kg of digestible protein. Oil cake contains vitamin E, B-complex vitamins, potassium, and phosphorus; it is low in sodium and calcium. It is fed to all types of farm animals, mainly as part of mixed feeds. [29–1443–1]

OIL MINING, SUBSURFACE, a method of petroleum extraction that is based on the digging of a system of underground mining excavations. The method is used to mine pools containing high-viscosity oils, or bitumens, and heterogeneous pools of medium-viscosity oil that are no longer productive by other methods. Oil may be mined either by washing or by drainage.

In washing, oil-bearing rock is shattered by, as a rule, drilling and blasting. At the working face, the rock is loaded into underground haulage cars by loading machines. The rock is then conveyed up the shaft to the surface, where it is processed in special installations to remove the petroleum fractions. Combined processing of the mineral raw materials is possible; after the petroleum fractions are removed, the containing rock may be used, for example, as a building material or as raw material for the chemical industry.

In drainage, oil is mined by means of boreholes drilled from previously dug mining excavations. Drainage is used in cases where the crude oil either is mobile or may be rendered mobile artificially, for example, by heating the productive formation. If the crude oil is made mobile by artificial means, the final production may be increased to 50–60 percent, as compared with the 5–6 percent achieved by other methods. Mine wells, which may be vertical, inclined, or horizontal, can be drilled to substantial depths. For example, the PBS-2T underground drill rig makes it possible to drill mine wells that are 300 m long and up to 370 mm in diameter. The oil is gathered in underground storage sumps and then pumped to the surface.

Subsurface oil mining has a number of technological advantages. Productive formations are directly accessible, so that losses of heat-transfer fluids before their injection into the formations are reduced to a minimum. In addition, a higher percentage of the oil in a formation is extracted, and fuller use is made of petroleum reserves. Finally, weather conditions do not affect any of the operations. However, subsurface oil mining requires that personnel work underground. Such mining is complicated by the presence of gas shows, a gas cap, bottom water or edgewater, and productive formations composed of loose ground or of quicksand.

In the USSR, the largest amount of experience in subsurface oil mining has been accumulated at the Iarega deposit in the Komi ASSR, where commercial subsurface oil mining has been carried out since 1939. The method of using a heat-transfer fluid to heat the deposit's productive formation has been tried and developed there since 1968. Mining conditions permit subsurface oil mining at certain fields in Azerbaijan, Kazakhstan, Groznyi Oblast (the Chechen-Ingush ASSR), and Krasnodar Krai.

V. P. TABAKOV [29–908–1]

ONE STEP FORWARD, TWO STEPS BACK (subtitled *The Crisis in Our Party*), a work by V. I. Lenin that develops a Marxist theory of the proletarian party, elucidates the organizational principles of Bolshevism, and defines the political significance of the division of the RSDLP into Bolsheviks and Mensheviks at the Second Party Congress. Written between February and May 1904 and published in May 1904 in Geneva, *One Step Forward, Two Steps Back*, is included in the fifth Russian edition of Lenin's works (*Poln. sobr. soch.*, vol. 8, pp. 185–414).

With the approach of revolution in Russia, it became of paramount importance to explain to the party's masses the reasons for the split at the Second Congress of the RSDLP in 1903 and the nature of Bolshevism's struggle against Menshevism after the congress. Although they assured the party of their agreement with the Bolsheviks on matters of principle, the Mensheviks stepped up their divisive activities. In addition to distorting the nature of disagreements within the party, they declared the Leninists' victory at the Congress a chance occurrence and stated that there was no obligation to carry out the resolutions of the congress and the party's central bodies. They viewed the subordination of the minority to the majority as a crude, mechanical suppression of the will and freedom of the party members, and they referred to party discipline as serfdom. In essence, they worked against the creation of a single, united party built on the principles of centralism, arguing instead that party organizations should remain independent of the Central Committee.

Lenin showed that the division into Bolsheviks and Mensheviks was a direct continuation of the division of Social Democrats into revolutionary and opportunist wings, which had surfaced during *Iskra*'s struggle against economism. Lenin pointed out that "the new division is based on a difference over questions of *organisation*, which began with the controversy over principles of

organisation (Paragraph 1 of the Rules) and ended up with a 'practice' worthy of anarchists" (*ibid.*, p. 373). The success of the congress was a step forward in the creation of a revolutionary party, whereas the divisive activity of the Mensheviks represented two steps back, for the masses could be prepared for revolution only if there were ideological and organizational unity in the party and a centralized direction of party organizations.

The Bolsheviks regarded the party as the leader of a class; the Mensheviks made virtually no distinction between the party and the class as a whole. Unmasking the Mensheviks' organizational opportunism, which had cropped up at the congress during a discussion of the first paragraph of the Rules—pertaining to party membership—and had developed into a system of opportunist views, Lenin showed that the Mensheviks' attempt to give every striker the right to call himself a member of the RSDLP erased the boundary between the vanguard and the rest of the working class. In the final analysis, this approach would doom the party to accommodating the most backward elements of the proletariat. The party, as the vanguard of the working class, must not be confused with the class as a whole. The party is the section of the working class with the greatest political awareness; armed with a knowledge of the laws of social development and class struggle, it is equipped to lead the proletariat.

The party is not only the vanguard but the organized vanguard of the working class. It will be able to fulfill its role as leader only if it is highly organized and disciplined and if its members are united in their will and their actions.

The party is the highest form of the proletariat's class organization. Its mission is to lead all mass working-class organizations, including professional, cooperative, youth, and women's organizations, uniting their efforts in the struggle against the exploiting classes. The party embodies the tie between the vanguard of the working class and the broad millions of the proletariat and all working people.

The party can become a strong and united organization only if it is built on the principle of centralism. In other words, the party must be structured and must operate according to a single set of rules; leadership must come from a single source—the party congress or, between congresses, the Central Committee; there must be a single discipline for the party's rank and file and its leaders; and the minority must be subordinate to the majority, and lower organizations to higher ones.

Lenin pointed out that centralism in no way contradicts democratism, which was characteristic of the Marxist party from its inception, and that when operating as a legal organization the party must be built on the principle of democratic centralism. For underground work, however, Lenin advocated the principle of centralism, since only it could guarantee the ability of the party to fight when subjected to severe repression by the authorities. A centralized and disciplined Marxist party, to be sure, is based on democracy within the party, collective leadership, criticism, and self-criticism.

Lenin's main point, which runs through the entire book, is the crucial importance for the proletariat of organization. The strength of the working class lies in organization: without organization the proletariat is nothing; organized, it is everything. Lenin wrote: "In its struggle for power the proletariat has no other weapon but organisation. The proletariat can, and inevitably will, become an invincible force only through its ideological unification on the principles of Marxism being reinforced by the material unity of organisation, which welds millions of toilers into an army of the working class. Neither the senile rule of the Russian autocracy nor the senescent rule of international capital will be able to withstand this army" (*ibid.*, pp. 403–04).

One Step Forward, Two Steps Back was distributed widely in local party organizations. It exerted a tremendous influence on party cadres and was a powerful ideological weapon in the battle against Menshevism. In 1907 the book was republished in the collection *After Twelve Years*, printed by the Bolshevik publishing house Zerno in St. Petersburg.

Lenin's book occupies an important place in the development of Marxist-Leninist theory and in the history of the CPSU and of the entire world communist movement. The Leninist principles for building a revolutionary proletarian party are of permanent value and have been confirmed by the experience of the world revolutionary movement.

As of Jan. 1, 1977, *One Step Forward, Two Steps Back* had gone through 151 printings; a total of 9,150,400 copies had been produced in 43 languages of the USSR and other countries.

Istoriia KPSS, vol. 1. Moscow, 1964. A. I. SEREDA [29–797–1]

OPTICAL SQUARE, a very simple geodetic instrument that is used to lay off angles that are multiples of 90° or of 45°.

In a prism square (see Figure 1), the direction of a ray originating from the flag on the right is changed by 90° after refraction and internal reflection. To lay off the angle by which the direction of the ray is changed, a second flag is set up in such a way that, when it is seen over the instrument, it is exactly above the image of the first flag in the instrument.

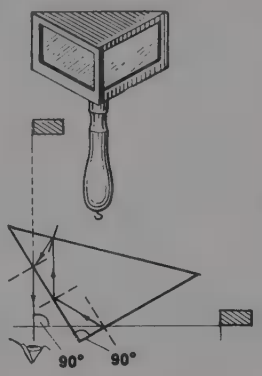

Figure 1. A prism square

Optical squares are used to solve geometric problems on a terrain and to carry out plane surveys. [29–1751–1]

OSCILLATION, FREQUENCY OF (also oscillation frequency), the number of complete oscillations per unit time. For harmonic oscillations, the frequency $f = 1/T$, where T is the period of the oscillations. The unit of frequency is one oscillation per second, which is called a hertz. A quantity that is often used is the angular frequency $\omega = 2\pi f$. [29–85–1]

OSCINELLA (frit flies), a genus of grain flies. There are several species, although the exact number is not known. Each species is usually injurious to one specific grain. The most common species are *O. frit*, which usually infests oats; *O. pusilla*, which infests barley; and *O. vastator*, which infests spring wheat. The last two species also infest winter rye, winter wheat, corn, and some herbs. The insects are widespread in regions where grains are cultivated. The body is black and measures 1.5–2 mm in length. Two or three generations are produced annually in the north, and as many as five in the south. The flies emerge in late April in the south and in late May or early June in the north. The eggs are deposited on young plants with no more than two or three leaves or in the spikelets. The larvae feed inside the stem on the embryo of the spike or on the developing caryopsis. The stems wither, and the central leaf dries up. Infested corn plants branch intensively, many stems become twisted, and the number of ears decreases sharply. The insects winter, usually in the larval phase, in the stems of perennial grasses and on the shoots of winter crops.

Measures to combat the flies include scuffling of the stubble, early fall-winter plowing of grain fields, early sowing of spike crops, sowing of corn and winter crops at the optimum time, early top-dressing of shoots with inorganic fertilizers, and treating of seeds and grain crops with pesticides.

ÖSEL, BATTLE OF (1719), an engagement between the Russian and Swedish navies on May 24 (June 4), 1719, near the island of Ösel (now Saaremaa), during the Northern War of 1700–21.

A Russian squadron of six ships of the line and a *shniava* (a light double-masted vessel for reconnaissance and messenger service) under Commander N. A. Seniavin came upon a Swedish force consisting of one ship of the line, one frigate, and one brigantine under Commodore Admiral Wrangel. The Russians gave chase. Under heavy artillery fire, first the frigate and brigantine and then the ship of the line surrendered.

The Russians took 387 Swedes prisoner; 50 Swedes were killed, and 13 were wounded. Nine Russians were wounded. The battle of Ösel was the first battle on the high seas in which the Russian Navy achieved victory without boarding the enemy's ships. [29–1693–5]

ÖSEL EPISCOPATE (also Saare-Läänemaa or Ösel-Vikskim Episcopate), a feudal state that was located in northwestern Estonia and included the province of Läänemaa and parts of the islands of Saaremaa and Hiiumaa. The total area of the Ösel Episcopate was approximately 7,600 sq km.

The episcopate arose as a result of the conquest of Estonia in late 1227 or early 1228 by the Order of Knights of the Sword, which subsequently, in 1237, merged with the Teutonic Order to form the Livonian Order. The state, which assumed its definitive form in 1234, was headed by a bishop who was a vassal of both the Holy Roman emperor and the pope. The bishop's see was first located at Lihula, but it was moved to Pärnu in 1251 and then to Haapsalu circa 1265.

During the 13th and 14th centuries, the Livonian Order strove to establish a unified Livonian state that would include the Ösel Episcopate. After the order was defeated by Russia in the Livonian War of 1558–83, the bishop sold his holdings in 1559 to the Danish king, Frederick II, who granted them to his brother Duke Magnus in 1560. Although the Ösel Episcopate was subordinated to Denmark in 1561, it survived as a separate entity on the island of Saaremaa until 1573. [29–1694–1]

OSMUNDA, a genus of perennial ferns of the family Osmundaceae. The stems are massive and usually short; they are topped by a crown of large leaves measuring as much as 3 m long. The pinnate leathery or filmy leaves are divided into vegetative and spore-bearing parts. Sometimes there are separate vegetative and spore-bearing leaves. There are about 15 species, growing in humid and swampy regions, primarily in the subtropics of Eurasia, Africa (including Madagascar), and the Americas. The USSR has three species. The royal fern (*O. regalis*), with leaves up to 1.5 m long, occurs in western Transcaucasia; the two other species are found in the Far East. Some species are ornamental. [29–645–1]

ØVERLAND, ARNULF. Born Apr. 27, 1889, in Kristiansund; died Mar. 25, 1968, in Oslo. Norwegian poet.

Øverland, who took part in the socialist movement, spent the years 1941 to 1945 in the Sachsenhausen and other concentration camps. Feelings of melancholy and loneliness pervade the collections he published between 1910 and 1920. Such collections as *I Conjure Thee* (1934) and *The Red Front* (1937) protest against capitalism; they express sympathy for the USSR and the Spanish people's struggle for freedom. Øverland's poems of the war years (collected in *We Shall Live Through All*, 1945) called for a struggle against fascism. His later collections of verse include *The Smoking Candle* (1960) and *On Nebo Mountain* (1962). He also wrote short stories, plays, and works on linguistics.

Øverland opposed the modernist school in postwar Norwegian poetry. At the same time, however, the poet retreated from his socialist ideals. Øverland served as chairman of the Norwegian Writers' Union in 1952.

OXALIC ACID, HOOC—COOH, the simplest dibasic carboxylic acid. A colorless crystalline compound, oxalic acid has a melting point of 189.5°C. Its solubility in water is 10 g per 100 g H_2O at 20°C and 120 g at 100°C. Oxalic acid is poorly soluble in alcohol and ether and is insoluble in benzene and chloroform. It is a relatively strong acid ($K_1^{25} = 3.6 \times 10^{-2}$). It forms the hydrate $C_2H_2O_4 \cdot 2H_2O$ (melting point, 101.5°C), as well as acid and neutral salts (oxalates), esters, amides, and other derivatives.

Salts of oxalic acid are found in plants—for example, its acid potassium salt is found in sorrel (genus *Oxalis*, hence the name). The acid forms in tissues as a metabolic product and, together with the oxalic acid in food, is excreted with urine as potassium oxalate. Oxalates participate in the formation of stones in the kidneys and urinary bladder in cases of disorders of mineral metabolism. Oxalic acid is formed in oxalic acid fermentation.

Oxalic acid was first synthesized in 1842 by F. Wöhler from cyanogen. It is produced industrially by the pyrolysis of sodium formate, HCOONa. It is used as mordant in cloth printing; it is also used in the production of dyes and inks, as a bleaching agent, and as a precipitating agent for rare earths. [29–1570–3]

PADUS, a genus of low trees and, rarely, shrubs of the family Rosaceae. The simple, alternate leaves have early-falling stipules. The white flowers are gathered into racemes. The fruit is a drupe.

There are about 15 species (according to other data, as many as 27), distributed in Eurasia and North America. The USSR has four native species and several others under cultivation. The bird cherry or cluster cherry (*P. avium*, formerly *P. racemosa*), a tree reaching 17 m in height and 40 cm in diameter, is found in the European USSR, Western Siberia, the Caucasus, and certain regions of Middle Asia. The tree grows mainly on rich soils, often in river forests. It is cultivated in orchards and parks. The flowers have a strong fragrance; the plant is a good nectar-bearer. The fruits are used as food and for coloring alcoholic beverages. Teas or infusions made from the fruits are used as binding agents to treat diarrhea. The bark yields dye, and the close-grained wood is used in the production of various articles. The closely related *P. asiatica* grows in Eastern Siberia and the Far East. *P. ssiori* and *P. maackii* grow in the Far East; the latter was used by I. V. Michurin to develop *Cerapadus*. The American chokecherry (*P. virginiana*) and wild black cherry (*P. serotina*) are commonly cultivated.

The genus *Padus* is closely related to the genus *Cerasus* and somewhat related to the genera *Laurocerasus*, *Prunus*, and *Amygdalus*. The five genera are often united in the single genus *Prunus*. [29–195–2]

PALE OF SETTLEMENT, the part of the Russian empire in which Jews were permitted to reside on a permanent basis. It included the provinces of Bessarabia, Vil'na, Volyn', Grodno, Ekaterinoslav, Kovno, Minsk, Mogilev, Podol'sk, Poltava, Tavrida, Kherson, Chernigov, and Kiev.

The pale of settlement was created in the late 18th century, when the Right-bank Ukraine, Byelorussia, and Lithuania—all with large Jewish populations—were ceded to Russia in the partitions of Poland. Only "local Jews" were permitted to live in Courland Province, the Caucasus, and Middle Asia. Within the pale of settlement, Jews were forbidden to live in the villages or in the cities of Kiev, Sevastopol', and Yalta. Those permitted to live outside the pale were merchants of the first guild, persons with higher and specialized education, artisans, and soldiers fulfilling compulsory military service; the descendants of persons in these three categories were also authorized to live outside the pale.

For the Jews the pale of settlement was the most onerous burden resulting from their unequal status as a nation (*natsiia*, nation in the historical sense). The pale of settlement was abolished by the law of Mar. 20 (Apr. 2), 1917, On the Abolition of Religious and National Restrictions.

PALPUS, a segmented appendage of the jaws (mandibles and first and second maxillae) in crustaceans, myriapods, and insects, equipped with various sense organs (tactile organs and chemoreceptors). The palpi are well developed and completely represented in crustaceans; in myriapods and insects there are no palpi on the mandibles. In many insects, especially those with a sucking-type mouth apparatus, the palpi are reduced. [29–1620–3]

PANEL-GLUING MACHINE, a woodworking machine for the fabrication of panels of various sizes by gluing together planed or sometimes unplaned wooden beams, edgings, or scraps of boards. A distinction is made between static and continuous panel-gluing machines.

A static panel-gluing machine has supports on which clamping mechanisms are mounted. The clamping mechanisms, which may be screw, pneumatic, or hydraulic devices, tightly squeeze the parts being glued together against one another and prevent them from swelling. Static panel-gluing machines have steam or electric heaters to accelerate the hardening of the glue.

In continuous panel-gluing machines, panels are continuously glued together. Workpieces smeared with glue are squeezed tightly against one another, pass through a heating area, and are heated to harden the glue. After the workpieces emerge from the heating area, they are cut into the required sections.

Old manually operated fan-type and conveyor-type assemblers (*vaimy*) may also be classified as panel-gluing machines. In such machines, clamped panels complete one turn on a horizontal shaft or a conveyor chain; the glue hardens as the panels turn. The panels are then removed, and new workpieces are placed in the empty units. [29–1613–3]

PARALLEL RULE, a device for uniform hatching, used in drafting. The principal elements of a parallel rule are a straightedge with a protractor attachment, a fastening yoke, a rod, and a shift lever with a return spring. When the lever on the rod is pressed, the rod carrying the yoke with the straightedge is moved by a predetermined step ranging from 0.2 to 10 mm. The yoke may be fastened at any point on the rod up to a distance of 100 mm. The protractor attachment has a stop that allows the straightedge to be set at an angle from 0° to 180°. Self-contained parallel rules are attachable to any spot on the drawing by means of pins; other types are made in unit with drafting machines. [29–1496–1]

PARITY, a quantum-mechanical characteristic of the state of a physical microparticle, for example, a molecule, an atom, an atomic nucleus, or an elementary particle. Parity represents the symmetry properties of the wave function of such a microparticle with respect to mirror reflection. In processes resulting from strong interactions and from electromagnetic interactions, the law of parity conservation holds; that is, a physical system having mirror symmetry of a definite type in the initial state retains that symmetry at all later moments in time. The conservation of parity leads to a number of selection rules in the electromagnetic radiation of atoms and atomic nuclei, in nuclear reactions, and in reactions involving transformations of elementary particles.

The law of parity conservation may be demonstrated by using the Zeeman effect as an example. When a magnetic field is applied, the intensity of the radiation in individual spectral lines remains symmetric with respect to the plane perpendicular to the field but is no longer identical in all directions. The radiation in the direction of the magnetic field is the same as the radiation in the opposite direction. If we imagine a system—in the form of a current-carrying circular conductor with a specimen placed at the center of the circle—for observing the Zeeman effect, the mirror symmetry of the system becomes obvious, but only on the condition that all the elementary particles composing the system have mirror symmetry. Thus, the law of parity conservation is based on the assumption that all electrons, protons, and other particles are transformed into themselves under mirror reflection.

Instead of mirror symmetry with respect to a plane, it is more convenient to consider an operation that entails the inversion of coordinate axes: $\mathbf{r} \rightarrow -\mathbf{r}$ or $x \rightarrow -x$, $y \rightarrow -y$, $z \rightarrow -z$ (*see* SPACE INVERSION).

The law of parity conservation governs the transformation properties of physical quantities under the inversion of coordinate axes. Thus, from the assumption that a charged particle—for example, an electron—is transformed into itself under inversion, it follows that electric charge q is a scalar, current density $\mathbf{j}$ and electric field strength $\mathbf{E}$ are true (or polar) vectors, and magnetic field strength $\mathbf{H}$ is an axial vector (or a pseudovector): $q \rightarrow q'$, $\mathbf{j} \rightarrow -\mathbf{j}'$, $\mathbf{E} \rightarrow -\mathbf{E}'$, $\mathbf{H} \rightarrow \mathbf{H}'$.

The law of parity conservation is violated in weak interactions, which—in particular—are responsible for the beta decay of nuclei. The violation was predicted in 1956 by Tsung Dao Lee and Chen Ning Yang. It was confirmed experimentally in 1957 by Chien Shiung Wu and co-workers in the beta decay of nuclei and by the American physicists L. Lederman and R. Garwin, as well as other scientists, in the decay of muons. Parity is also not conserved in the decays of charged pions, kaons, and hyperons. The Soviet physicists Iu. G. Abov, V. M. Lobashev, and others discovered the nonconservation of parity in weak nucleon-nucleon interactions.

A diagram of Wu's experiment is shown on the left in Figure 1. A specimen containing the radioactive isotope ^{60}Co was placed in the magnetic field $\mathbf{H}$ of a circular current. The field $\mathbf{H}$ oriented the relatively large magnetic moments of the ^{60}Co nuclei in the direction parallel to $\mathbf{H}$. The short arrow on the left in Figure 1 indicates the direction of the electron velocities within the conductor. As in the example of the Zeeman effect, Wu's system was mirror symmetric with respect to the plane in which the circular current flowed. If the law of parity conservation held, the intensity of the electron (e^-) emission during β^- decay should have been the same on both sides of the plane in which the current flowed. However, a pronounced asymmetry was observed in the experiment: 40 percent more electrons were emitted on one side of the plane than on the other side.

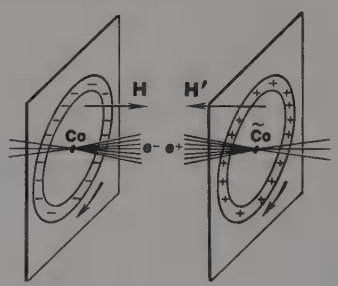

Figure 1. Diagram illustrating Wu's experiment (left) and its mirror image (right)

From Wu's experiment, it follows that magnetic field strength is a polar vector rather than an axial vector. This is not inconsistent with the equations of electrodynamics if we assume that current density and electric field strength are axial vectors and—at the same time—that electric charge is a pseudoscalar. The identification of charge as a pseudoscalar means that, under mirror reflection, electrons are transformed into positrons (e^+) and, in general, all particles are transformed into their respective antiparticles. The possibility of such an interpretation of reflection was pointed out by the American scientists E. Wigner, G. Wick, and A. Wightman as early as 1952.

L. D. Landau referred to mirror reflection accompanied by the replacement of all particles by their antiparticles as combined inversion. The hypothesis that the laws of nature are symmetric with respect to combined inversion is expressed by the law of the conservation of combined parity, which is usually called the law of CP conservation. When the law of parity conservation is replaced by the law of CP conservation, the scheme of Wu's experiment is no longer mirror symmetric, since the β^+ decay of an anticobalt nucleus, $\bar{C}o$, in the magnetic field of a circular positron current is the mirror image of her experiment (Figure 1, on the right); an anticobalt nucleus consists of antiprotons and antineutrons. Since the charge of the positron is positive, the sign of the current changes if the positrons move in the same direction as the

electrons. A change in the sign of the current leads to a change in the sign of the magnetic field ($\mathbf{H}'$).

Thus, the law of parity conservation is approximate and holds only when weak interactions are ignored. The conventional treatment—where, for example, $\mathbf{H}$ is an axial vector—of the transformation properties of electromagnetic quantities with respect to the inversion of coordinate axes is valid to the same extent to which the law of parity conservation holds.

In quantum theory, the parity of a state of a system consisting of n particles is defined as the eigenvalue of the parity operator P, which inverts space. The action of the operator P on the state vector $\psi(\mathbf{p}_1, \ldots, \mathbf{p}_n)$ consists in a change of the signs of the particle momenta $\mathbf{p}_i$ and in the multiplication of the parity of the state vector by the product $\Pi_1 \ldots \Pi_n$ of the intrinsic parities of the particles. Intrinsic parity is an inherent property of a particle and is equal to either $+1$ or -1. Particles for which $\Pi_k = 1$ are said to have even parity, while particles for which $\Pi_k = -1$ are said to have odd parity. For example, the intrinsic parity of neutral pions is odd. The intrinsic parities of antiparticles with half-integral spin are the opposite of those of the respective particles. For this reason, in particular, mesons consisting of a quark and an antiquark with zero orbital angular momentum—for example, pions, kaons, rho mesons, and omega mesons—have odd intrinsic parity. The operator P does not act on spin projections or on charges. The eigenvalues of the operator P are equal to ± 1. States with $P = 1$ are called states of even parity; states with $P = -1$ are known as states of odd parity.

The definition of parity leads to two rules for determining the parities of physical systems consisting of several particles. First, the parity of a system consisting of n particles with orbital angular momenta $\hbar l_1, \ldots, \hbar l_n$, where $\hbar$ is Planck's constant and l_i are integers, is equal to

$$\Pi_1 \ldots \Pi_2(-1)^l 1 + \cdots + l_n$$

Second, the parity Π_{12} of a complex system consisting of two subsystems with respective parities Π_1 and Π_2 is equal to $\Pi_1\Pi_2(-1)^L$, where $\hbar L$ is the orbital angular momentum associated with the relative motion of the subsystems.

Electromagnetic field quanta have neither intrinsic parity nor orbital angular momenta. The parity of a quantum of electromagnetic radiation, or a photon, is determined by the quantum's multipole order (*see* MULTIPOLE). The parity of an electric 2^l-pole is equal to $(-1)^l$, while the parity of a magnetic 2^l-pole is equal to $(-1)^{l+1}$. Therefore, the parity of a physical system is conserved when an electric multipole quantum with even l or a magnetic multipole quantum with odd l is emitted or absorbed. It is reversed when an electric multipole quantum with odd l or a magnetic multipole quantum with even l is emitted or absorbed. The parity selection rules for the electromagnetic radiation of atoms and nuclei result from the fact that, for identical multipole orders with all other conditions being equal, magnetic multipole radiation is substantially weaker than electric multipole radiation. The ratio of the probabilities of magnetic and electric multipole radiation is of the order of $(2\pi R/\lambda)^2$, where R is the linear size of the radiator and λ is the wavelength of the radiated quantum. As a rule, the ratio is much smaller than unity for both nuclei and atoms, so that the parity selection rules are markedly exhibited.

The law of parity conservation, which is also called P invariance, is formulated as the conservation of the quantity P in strong and electromagnetic interactions.

The concept of the intrinsic parity of a particle and, thus, of the parity of a state contains a certain degree of ambiguity, which is associated with the impossibility of comparing the parities of states that differ in the values of just one of the conserved charges, for example, electric charge or baryon charge. Therefore, in particular, the parity of the vacuum state and the parities of the proton, the neutron, and the electron are arbitrary and may be assigned positive values. However, in this case, the parities of, for example, a pion, the positron, and the antiproton become well defined and must be assigned negative values.

The fundamental question of the symmetry of real space with respect to mirror reflection is closely associated with the concept of parity. The methods of group theory have been used to prove that, if space has mirror symmetry, either the law of parity conservation or the principle of CP invariance must be strictly satisfied. The violation of both the law and the principle in weak interactions has been established experimentally. Therefore, grounds exist for postulating that either space does not have symmetry between left and right or such symmetry is broken in certain types of interactions. An example of such interactions is the interactions that result in the decay of the long-lived neutral kaon, $K^0_L \rightarrow 2\pi$.

PARITY OF A STATE, the parity of an energy state of a physical system, that is, the parity of a wave function. Such a characteristic of energy states is possible for a system of particles in which electromagnetic or nuclear forces that conserve parity act between the particles.

When weak interactions are taken into account, a state with a given parity acquires a small admixture of the opposite parity. In atomic nuclei, the relative magnitude of the admixture is of the order of 10^{-6}–10^{-7}.

If an energy state is degenerate, so that wave functions with different parities are associated with the state (as is the case with, for example, excited states of the hydrogen atom), states described by the superposition of such wave functions are possible; that is, the degenerate state may not have a definite parity, even if the forces acting in the system conserve parity.

S. S. GERSHTEIN [29–359–1]

PART AND WHOLE, philosophical categories expressing the relationship of an aggregate of objects (or elements of a single object) to the connection that joins the objects together and endows the aggregate with a new set of integrative properties and regularities not inherent in the objects when separate. As a result of this connection, a whole is formed, with the individual objects representing its parts.

The categories of the part and the whole also characterize the general movement of knowledge, which usually begins with the undifferentiated representation of the whole, then proceeds to the analysis of the whole and its breakdown into parts, and completes the process by reconstructing the object in the mind in the form of a concrete whole. These principles pertaining to the knowledge of whole objects were formulated by K. Marx in his "Economic Manuscripts of 1857–59" (see K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 46, part 1). The overall strategy of scientific knowledge, as it develops in any given period, is determined to a significant extent by the particular treatment of the categories of the part and the whole and the specific interpretation of the related question of wholeness.

The problem of the relationship of parts and wholes, raised in ancient times by Plato and Aristotle, has been examined by all the important schools of philosophy. The scientifically oriented materialist views of F. Bacon, T. Hobbes, J. Locke, and the 18th-century French materialists were usually associated with a me-

chanistic and summary conception of the whole, borrowed from mechanics and later from classical physics. In classical natural science, knowledge of the whole was sought only from the point of view of its composition and structure. In contrast, the idealist philosophers—Plato, the medieval Scholastics, and, to a certain extent, G. von Leibniz—insisted that the whole could not be reduced to the sum of its parts. Only the products of mental activity were seen by them as truly whole, while material entities were regarded as mechanical wholes, or dead aggregates.

The gap between these contrasting concepts—the mechanistic sum of the parts at one extreme and the mystical mental whole at the other—leads to the following important antinomies with respect to parts and wholes:

(1) Thesis: The whole is equal to the sum of its parts. Antithesis: The whole is greater than the sum of its parts.

(2) The parts precede the whole. The whole precedes its parts.

(3) The whole is causally determined by its parts. Wholeness contradicts and excludes causality.

(4) The whole is understood through knowledge of its parts. The parts, as products of the division of the whole, can be understood only through knowledge of the whole.

The classical German philosophy of F. von Schelling and G. Hegel introduced the distinction between the inorganic and the organic (or self-developing) whole; the organic whole, however, was associated with nonmaterial development only, and not with matter. In the 19th and 20th centuries the relationship between parts and wholes was treated in similar terms in the various idealist schools of thought, such as neovitalism, holism, and intuitivism.

K. Marx critically reinterpreted the traditions of classical German philosophy and formulated a set of principles for the study of organic wholes, including the method of ascent from the abstract to the concrete and the dialectical interpretation of analysis and synthesis. He was also the founder of the methodology for the scientific study of society as a whole. Dialectical materialism provides a rational explanation of the dialectics of parts and wholes by combining the data of theoretical conceptions and disciplines based on the integral approach to objects—for example, the concept of integrative levels in theoretical biology and the results of research in genetics, ecology, physiology, psychology, and linguistics.

It has been demonstrated not only theoretically but also on the basis of experimental data that the whole cannot be reduced to the sum of its parts in objects that have a complex structure. The formula "the whole is greater than the sum of its parts" has proved inadequate to resolve the problem, since the formula implicitly presumes additivity (or summariness, which does not constitute wholeness) of the properties of the whole; wholeness here seems to be what remains after the sum of the parts is subtracted from the whole. The answer is that the whole is characterized by new properties and qualities, which are not inherent in the individual parts (or elements) but which appear as a result of the latter's interaction within a particular system of connections.

This property of any form of a whole, which may be called the integrative property, also makes it possible to understand all the other specific properties of the whole. Such properties include the appearance of something new in the process of development, the emergence of new types of wholeness, the appearance of new structural levels and their hierarchical order, and the distinction between organic and inorganic wholes—a distinction based on the fact that in inorganic wholes (such as atoms or molecules) the properties of the parts, even though reflecting the nature of the whole, are determined primarily by the internal nature of the parts, whereas in organic systems (such as biological or social objects) the properties of the parts are wholly determined by the properties of the whole.

Further logical contradictions arise in the general formulation of the question of what comes first—the whole or its parts. In the relationship of parts and wholes, as Hegel showed early on, neither can be considered without the other. The whole is inconceivable without or before the parts; on the other hand, a part outside the whole is no longer a part but a different object, since the parts of the whole express the nature of the whole and acquire its specific properties.

The relationship between the parts of an organic whole, as well as the relationship between the parts and the whole, is not a simple functional dependence but a much more complex system of different types of connections, including structural and genetic connections and the connections of subordination and control. Within this system, causes are simultaneously effects, and what is posited is simultaneously a premise. The interdependence of the parts here is such that it appears not in the form of a linear causal series but rather as a special type of closed circle within which each element of the connection is both a condition of and conditioned by the next element (see K. Marx, *ibid.*, p. 229). This structural approach to the whole is not an alternative to causal explanation; it merely demonstrates the inadequacy of univocal causality in the analysis of a complex system of connections. Moreover, the principle of structural explanation may itself be regarded in a certain sense as an extension of the principle of causality.

Modern knowledge also provides the solution for a well-known cognitive paradox—namely, how can the whole be known before the parts if this presupposes knowledge of the parts before knowledge of the whole? The parts and the whole become known at the same time; the parts are identified and analyzed as elements of the given whole, and as a result of synthesis the whole emerges as dialectically broken up into and consisting of its parts. In the final analysis, study of the parts is the only possible means of studying the whole. At the same time, the results of the study of the parts are incorporated into the system of scientific knowledge only because they represent new information about the whole. The analysis of the dialectical interrelation of parts and wholes is a very important methodological principle of scientific knowledge.

PARTIAL DISCHARGE, an electrical discharge that occurs in gaseous inclusions within electrical insulation or over contaminated or damp sections of the surface of such insulation. Partial discharges cause solid insulation to age or deteriorate. To avoid the occurrence of partial discharges, materials used as insulation are subjected to special treatment, such as vacuum drying or the impregnation of voids with an electrically strong dielectric. In addition, whenever possible, the surface of insulation is kept free of contamination and moisture. [29–80–4]

PARTICLE, a member of a lexical-grammatical class of words that express the attitude of the speaker toward an utterance and that may be used to produce certain grammatical forms. An auxiliary part of speech, the particle is not a sentence part.

Particles exist in many languages, and the Slavic languages have a rather extensive system. In Russian, particles are divided into several semantic-functional types. Syntactic particles are used in the formation of the subjunctive, imperative, and optative moods (*by, pust', da, davai, davaite*). Negative particles include *ne* and *ni*. Subjective modal particles modify the sense of other words or entire sentences; they include intensive particles (*ved', dazhe, -to, zhe*), emphatic particles (*tol'ko, lish'*), interrogative particles (*razve, neuzheli, li*), and exclamatory particles (*kak, chto za*). Particles are also used as affixes in the formation of pronouns and adverbs (*koe-, -libo, -nibud', -to*).

PARTICULAR SOLUTION. A particular solution of a differential equation $F(x, y, y', \ldots, y^{(n)}) = 0$ is a solution $y = \phi(x)$ obtained from the general solution $y = \phi(x, C_1, \ldots, C_n)$ of the equation for some specific choice of the arbitrary constants $C_1, \ldots, C_n$. For example, the general solution of the equation $y'' + y = 0$ is $y = C_1 \cos x + C_2 \sin x$; if we set $C_1 = 2$ and $C_2 = -1$, we obtain the particular solution $y = 2 \cos x - \sin x$. [29–82–2]

PARTS OF SPEECH, the fundamental word classes in a language, distinguished according to the similarity of the words' syntactic, morphological, logical, and semantic properties. Autonomous parts of speech include the noun, verb, adjective, and adverb; functional parts of speech include the conjunction, preposition, particle, and article. Numerals, pronouns, and interjections are also traditionally considered parts of speech.

Words can be classified according to the positions they occupy in a sentence. A part of speech will then include all words that can occupy identical syntactic positions in a sentence or that can perform identical syntactic functions. Of importance here is not only the set of syntactic functions, but also the degree to which each of the functions is characteristic of the particular part of speech. The functions are divided into primary and secondary according to specific morphological or syntactic restrictions. Thus, in Russian both the noun and the verb can function as subject (*chelovek liubit*, "man loves"; *kurit'—zdorov'iu vredit'*, "to smoke is to harm one's health") or as predicate (*Ivanov—uchitel'*, "Ivanov is a teacher"; *derevo gorit*, "the wood burns"). However, for the verb the predicate function is primary and the subject function is secondary, but for the noun the subject function is primary and the predicate function is secondary. For example, a verb can only be the subject with a nominal predicate, but a noun can be the subject with any predicate. A sentence with a verb subject can be transformed into a sentence with a noun subject (*kurenie vredno dlia zdorov'ia*, "smoking is harmful to one's health"), but the reverse is not true. A noun predicate requires a copulative verb in order to express tense and mood (*Ivanov byl/-byl by uchitelem*, "Ivanov was/would have been a teacher"), which is not true of a verb predicate. In Chinese both verb and adjective can function as an attributive, but in doing so the verb, unlike the adjective, requires the special adjectival suffix *-tê*.

Some scholars question the validity of considering pronouns and numerals separate parts of speech in most languages, since words of these classes ordinarily vary in their syntactic functions and from this point of view belong to different word classes. For this reason they are often considered subclasses of other parts of speech. (In Russian, for example, compare the noun numerals *tri*, "three," and *chetyre*, "four," with the adjectival numerals *pervyi*, "first," and *vtoroi*, "second.")

Each part of speech has its own set of characteristic grammatical categories; the set of categories embraces an absolute majority of the words of the particular part of speech. This serves as a morphological criterion for distinguishing parts of speech in inflected languages. In Russian, for example, number, case, and gender (as a word-classifying category) are characteristic of the noun, and degrees of comparison, number, case, and gender (as an inflectional category) are characteristic of the adjective. In Burmese, however, the adjective and verb are not contrasted in this way, since words corresponding to both adjectives and verbs in other languages have degrees of comparison.

The distribution of words by parts of speech is governed in all languages by certain semantic regularities that serve to differentiate the parts of speech semantically. In Russian the class of nouns includes words denoting objects (*stol*, "table"), qualities (*krasnota*, "redness"), and actions (*khozhdenie*, "walking"); however, the majority of nouns not denoting objects are derived, and the majority of nonderived nouns denote objects. This regularity imparts to the class of nouns the general meaning of objectness. In the same way, the general meaning of action or state is established for the verb, of quality for the adjective, and of action or quality attribute for the adverb.

The system of parts of speech taught in modern school grammars stems from the works of the Alexandrian philologists, such as Dionysius Thrax and Apollonius Dyscolus, who distinguished nominals, verbs, participles, adverbs, articles, pronouns, prepositions, and conjunctions according to mixed morphological, semantic, and syntactic criteria. In this system nominals included nouns, adjectives, and numerals. (In contrast, Plato combined the adjective and verb on the basis of logical syntactic relations.) The system of the Alexandrian philologists also influenced the Arab grammatical tradition. The Middle Ages and the Renaissance, during which logical-semantic criteria were stressed as the basis for the existence of parts of speech, introduced no significant changes into the system. The development of comparative-historical linguistics placed morphological characteristics in the forefront and was responsible for a purely morphological approach to the problem of parts of speech (with the additional influence of the Indian grammatical tradition). The new approach, as reflected in the works of F. F. Fortunatov, denied the existence of parts of speech in isolating languages. In the 20th century linguistics refused to recognize that word classes analogous to the parts of speech of inflected languages can be distinguished in isolating languages, a fact previously demonstrated by H. C. von der Gabelentz (the syntactic criterion establishes word classes in inflected languages that essentially coincide with morphological parts of speech). With the syntactic approach all languages have parts of speech, and difficulties arising from the morphological approach are avoided (such as the lack of morphological marking in the classification of indeclinable Russian nouns, such as *pal'to*, "overcoat").

Parts of speech differ from language to language. The differences concern not only which parts of speech a language has, but also what words are subsumed under each part of speech. Thus, Russian, French, and Latin distinguish nouns, adjectives, verbs, and adverbs. Several North American and African languages do not differentiate adverbs from adjectives. Chinese distinguishes nominals, predicatives (verbs and adjectives), and adverbs. In some languages, such as the American Indian language Yuma, only nominals and verbs are distinguished. Differences as to what words are subsumed under particular parts of speech can be observed by comparing Hausa, in which words corresponding to the adjectives of other languages are in the same class as nouns, with Burmese, in which this type of word is in the same class as verbs. The most consistent contrast in different languages is between the nominal and the verb, although such a contrast has not been demonstrated as universal.

PASSIVE SONAR, a device that detects the source of acoustic vibrations or noise and determines the direction, or bearing, to the source. It is used primarily as a hydroacoustic direction finder.

Passive sonars operate in the range of sonic, ultrasonic, and infrasonic frequencies. They include fixed devices, installed on the floor of the ocean or a sea on special support structures or anchored buoys, and mobile devices, which are used on submarines, on certain types of surface vessels, in containers lowered into the water from helicopters, and on free-floating buoys.

Passive sonars consist of sonic detector, compensator, filter, amplifier, and display device. The detector is usually an acoustic antenna with the required directivity pattern (*see* DIRECTIVITY OF ACOUSTIC TRANSMITTERS AND RECEIVERS), equipped with up to several hundred hydrophones. The compensator turns the axis of the directivity pattern of the antenna toward the noise-producing object and determines the bearing. When a rotating antenna is used, the passive sonar usually has no compensator. The filter passes a specific band of acoustic frequencies. Filtering out low

frequencies helps increase the operating range of the direction finder, and filtering out high frequencies improves the ratio of signal to background noise and increases direction-finding accuracy. The amplifier increases the amplitude of the signals being received to the level necessary for display. The display may be a telephone, loudspeaker, or cathode-ray tube.

Special devices can be connected to passive sonars to analyze the spectrum of the acoustic signal being received and identify the objects emitting the noise by type (submarine, surface ship, torpedo, and so forth). The accuracy of target direction finding of modern passive sonars may be within fractions of a degree, and the operating range may be in the tens of kilometers.

PATTERN (Russian, *shablom*), in foundry production, an element of a gated pattern, consisting of a flat device whose working side has a highly accurate profile. A distinction is made between molding and control patterns. The former, in the form of wooden boards, are used in individual and small-series production; they take the place of a solid casting pattern or corebox in the manufacture of casting molds and mold cores for medium-size and large castings having the outline of a body of revolution (such as cups, vats, covers, and pulleys). The cavity of the mold or the working surface of the core is produced by rotating the molding pattern around its central axis (a core spindle is positioned at this place in the mold). Control patterns are made of plywood or sheet steel and are used for checking the accurate placement of cores in the cavity of a casting mold during assembly and preparation for pouring. M. N. SOSNENKO [29–792–1]

PEDIMENT, in geomorphology, a zone of unconsolidated deposits formed at the foot of an elevated region by the merging of alluvial fans. The pediment consists of detrital material carried down by rivers, ephemeral streams, and sheetwash or transported by the force of gravity. Depending on the predominant process of transport, various types of pediments are distinguished: alluvial-proluvial, diluvial-proluvial, and diluvial. Pediments sometimes reach a width of 20–25 km, for example, on the southern slope of the Dzungarian Alatau. [29–1283–1]

PELOBATIDAE, a family of tailless amphibians of the suborder Anomocoela. Outwardly, the Pelobatidae resemble toads or frogs. The body length reaches 10 cm. The family comprises nine genera, encompassing about 50 species. Pelobatids are distributed in Europe, northwestern Africa, and western and southeast Asia, including the Philippines and Indonesia, and on the Seychelle Islands and in North and Central America. The USSR has representatives of two genera: *Pelobates* (European spadefoots) and *Pelodytes* (*see* PELODYTES).

Members of the genus *Pelobates* have a large spade-shaped tubercule on the hind foot; the web on the feet is well developed. The genus includes four species, which are distributed in southern and central Europe, northwestern Africa, and western Asia. The USSR has two species—*Pelobates fuscus* and *Pelobates syriacus*—which are found in Armenia and Azerbaijan. *P. fuscus* measures up to 6.5 cm in length. It is distributed in the USSR from the western borders to the central regions of the Kazakh SSR in the east and Ciscaucasia in the south. It inhabits steppes, meadows, and the margins of pine forests, preferring light soils. A nocturnal animal, it burrows in the earth during the day or hides in the burrows of other animals. It emits a faint garlic odor, mainly in the spring. It feeds on insects, spiders, worms, and mollusks. It enters the water only during the egg-laying season. The eggs are arranged in several rows in a jelly-like string up to 50 cm long. The tadpoles often winter over and attain a length of up to 17.5 cm.

PENALTY FUNCTION METHOD, a method of reducing problems of finding a relative extremum of a function to problems of finding the absolute extremum.

An important application of the penalty function method is to problems of mathematical programming. Suppose we wish to minimize the function $\phi(x)$ on the set $X = \{x: f_i(x) \geq 0, i = 1, 2, \ldots, m\}$ of an n-dimensional Euclidean space. The function $\psi(x, \alpha)$, which depends on x and on the numerical parameter $\alpha > 0$, is called the penalty function (or penalty) for violation of the constraints $f_i(x) \geq 0, i = 1, 2, \ldots, m$. This functipn has the following properties: $\psi(x, \alpha) = 0$ if $x \in X$ and $\psi(x, \alpha) > 0$ if $x \in X$. Let us construct the function $M(x, \alpha) = \phi(x) + \psi(x, \alpha)$ and designate as $x(\alpha)$ any point of its absolute global minimum. Let

$$\phi^* = \inf_{x \in X} \phi(x)$$

The function $\psi(x, \alpha)$ is selected so that $\phi(x(\alpha)) \to \phi^*$ as $\alpha \to +\infty$. The function

$$\alpha \sum_{i=1}^{m} |\min \{f_i(x), 0\}|^q \qquad q \geq 1$$

often is selected as $\psi(x, \alpha)$. The selection of the specific form of the function $\psi(x, \alpha)$ involves both the problem of the convergence of the penalty function method and the problems that arise in solving the problem of absolute minimization of the function $M(x, \alpha)$.

In a somewhat more general formulation, the penalty function method consists in reducing the problem of minimizing the function $\phi(x)$ on a set X to the problem of minimizing some parametric function $M(x, \alpha)$ on a set whose structure is simpler, from the standpoint of effectiveness of the application of numerical methods of minimization, than that of X.

PENTATOMOIDEA (shield bugs), a superfamily of the order Hemiptera, including the families Pentatomidae, Scutelleridae, Cydnidae, and Plataspidae. The round or oval body is 1.6 to 41 mm long and is covered with a large shield extending to the front third of the abdomen or covering the abdomen completely. The insects feed on the vegetative and, especially, generative organs of plants. Species of the subfamily Asopinae feed on other insects. Of the approximately 4,000 species, about 350 occur in the USSR. Some species are injurious to agricultural crops. The grain pentatomoidea, especially *Eurygaster integriceps* and *Aelia*, are injurious to cereals. Species of the genus *Eurydema* attack vegetable crops, and *Nezara viridula* damages cotton and other plants. [29–1609–1]

PHOLIURUS, a genus of herbaceous plants of the family Gramineae. There is a single species, *P. pannonicus*, a medium-sized annual with an upward-bending or erect stem. The linear leaves are narrow and flat, and the inflorescence is a narrow cylindrical spike. The two flowered spikelets are flattened at the sides and are arranged in a double row on the spike's axis; they fall off completely during fruit formation. The upper glume is leathery, and the lemma is membranous. The plant is distributed in southeastern Europe, the Caucasus, southwestern Siberia, and Middle Asia. It grows on solonchak and slightly saline meadows and on solonetzes. During the spring and early summer, it is eaten by camels, sheep, and horses. [29–528–6]

PIG, in metallurgy, a small ingot of metal—such as pig iron, a nonferrous metal, or a ferroalloy—in the shape of a bar, usually with a contraction. Pigs are cast horizontally in a mold that is open at the top in, for example, casting machines. [29–777–3]

PILLOW LAVA, basic (andesitic or basaltic) lava extruded into water and consisting of a series of spheres that fit closely upon one another. A glassy hardening zone is observed on the edges of each sphere; in the center of some large spheres, divergent parting is observed. Pillow lava is found in volcanic oceanic beds in association with keratophyres and spilites. It also occurs as part of ophiolitic complexes. [29–865–2]

PILOT BALLOON, a small rubber balloon filled with hydrogen and released in free flight to determine wind velocity and direction at different altitudes or to establish the altitude of the lower boundary of clouds. The pilot balloon ascends at a nearly constant speed, calculated according to the lifting force and the weight of the balloon envelope. The altitude of the balloon is determined as the product of the vertical speed and the time between the moment of release and the moment of recording. The wind velocity and direction at different altitudes are computed according to simultaneous readings of the altitude of the balloon and the angles (elevation angle above the horizon and the azimuth) observed through an aerological theodolite. [29–870–3]

PIN, a cylindrical or tapered rod that is used to join parts together, often in a precisely determined position, or to transfer relatively small loads. Pins are employed in fixed joints. In order to insert a pin, the parts are joined together and secured. A hole is then drilled and reamed at the location in the parts where the pin is to be inserted. In contrast to a cylindrical pin, a taper pin may be used repeatedly without reducing the precision with which the parts are positioned. [29–1481–2]

PINCHING, removal of the tops of shoots or the top shoots from agricultural plants to improve the formation of fruit and to speed up ripening of the harvest. After pinching, the shoots stop growing, and there is an intensified flow of nutrients to the young fruit, which reduces self-thinning and creates the best conditions for development of the fruit. Pinching is used for cotton, grapes, and other crops.

Pinching or chopping cotton speeds up fiber maturation and boll opening and reduces plant lodging. The procedure is done when 14 to 16 productive branches have developed on a bush. The main stem is cut back 4–6 cm, and lateral shoots 2–3 cm. Cotton is chopped by a 4VKh-4 cultivator attachment at the same time that the interrow spaces are loosened or irrigation furrows are cut.

Pinching grape plants accelerates shoot maturation, promotes the accumulation of plastic substances in the shoots to improve winter-hardiness, and increases the sugar content of the fruit. Grapes are pinched when plant growth slows down, usually in the second ten days of August. The top one-fifth of shoots that have overgrown their trellises and the tops of lateral shoots are removed, leaving two or three leaves on each. Young grape plants are not pinched. [29–129–1]

PINE GROSBEAK (*Pinicola enucleator*), also pine bullfinch, a bird of the family Fringillidae of the order Passeriformes. The body length is about 22 cm, and the weight, about 50 g. The head and breast of the males are raspberry pink, and the back is brownish gray; the breast of the females is olive green. The pine grosbeak is distributed in the taiga zone of Europe, Asia, and North America. A sedentary bird, it will migrate long distances when there is no food. It nests in trees. The clutch contains three to five eggs. The diet includes seeds, buds, berries, and, sometimes, insects. The pine grosbeak is often kept in cages. [29–1620–4]

PINTAIL (*Anas acuta*), a bird of the family Anatidae. The body length is about 70 cm. The males weigh about 900 g; the females weigh less. The two middle rectrices are very long (hence the name). The pintail is widely distributed in Europe, Asia, and North America. In the USSR it is not found in the Far North, the southern European part, and Middle Asia; during the molting period in the summer, it is commonly seen in the Volga River delta and on the lakes of southwestern Siberia and Kazakhstan. It is a migratory bird, and in the USSR it winters on the southern Caspian Sea. The pintail prefers shallow lakes. It nests in dry places. The clutch contains nine or ten greenish white eggs, which are incubated for 22 to 23 days. The diet consists of plants and animals. The pintail is a game bird. [29–1195–3]

PISTON ROD, a round rod that connects a piston to a slide block in reciprocating machinery—for example, pumps, compressors, steam engines, and some internal-combustion engines—or in the hydraulic or pneumatic mechanism of a reciprocating drive. A piston rod is used when the compartments formed on both sides of a piston are employed. When only one of the compartments formed in a cylinder of a reciprocating machine is used, a piston rod is usually not provided and a connecting rod is connected directly to the piston.

A unilateral piston rod is located on one side of a piston and passes through one head cover. A bilateral piston rod passes through two head covers; such a piston rod is used to provide better alignment of a heavy piston in steam-driven machinery or to connect a second cylinder in a compressor.

In some reciprocating hydraulic drives, a cylinder is attached to the moving part, or table, of a machine and a piston rod is attached to the bed. Hydraulic fluid is supplied through the piston rod to the compartment formed in the cylinder.

The diameter of a piston rod is usually determined by the rod's strength, stiffness, and stability. However, in reciprocating hydraulic drives, it is sometimes determined by the required velocity ratio of the to-and-fro motion at a constant pump capacity.

N. Ia. Niberg [29–1482–2]

PIT, a shallow (up to 25 m deep) vertical or, less often, inclined mining excavation that is sunk from the surface. Pits are used for various purposes, such as the exploration of mineral deposits, ventilation, the raising of water, the hauling of materials, and the lowering and hoisting of people. [29–1552–1]

PITCH, SCREW-THREAD, the distance between parallel sides of the profiles of two adjacent thread forms measured along the axis. The pitch is usually measured along a line on which the width of the thread forms is equal to the width of the groove. Multiple threads have both a pitch and a lead; the latter is defined as the distance through which the screw is displaced in one full turn in a stationary nut, that is, the pitch of one screw line of the thread. The lead is equal to the product of the screw-thread pitch and the number of starts; for single-start threads the lead is equal to the pitch. [29–799–2]

PLAGUE, an acute infectious disease of man and animals, classified as a quarantine disease. The causative agent is the plague bacillus, *Pasteurella pestis*, discovered in 1894 by the French scientist A. Yersin (1863–1943) and the Japanese scientist Kitasato Shibasaburo (1852–1931). It is a coccoid gram-negative bacillus that grows well on ordinary culture media and is sensitive to physical and chemical factors, as well as to ordinary disinfectants. It dies within one minute of exposure to a temperature of 100°C.

Plague epidemics periodically swept many countries. The first pandemic, known in the literature as Justinian's plague, occurred in the sixth century in the Eastern Roman Empire, affecting many countries and killing about 100 million persons in 50 years. The second pandemic, known as the Black Death, began in the 14th century. The third, which broke out at the end of the 19th century, was spread by ship rats to more than 100 ports in various countries. Occurrences of plague were recorded from the 14th century on in central and northwestern Russia, including numerous occurrences in Moscow. It occurred in Transbaikalia, Transcaucasia, and the Caspian Region in the 19th century and in Odessa and other Black Sea ports at the end of the 19th and early 20th centuries, where it was brought in by plague-infected rats. Major epidemics were recorded in India in the 20th century.

Plague is characterized by natural endemism, associated with desert, steppe, and mountain landscapes, where the epizootic process is maintained by certain rodent species; however, other rodents, as well as hares, camels, and other mammals, are also dangerous to man. The epidemiological danger increases when plague is introduced into populations of commensal ro-

dents, such as rats. The disease is transmitted to humans by animals through fleas; less common is infection as a result of direct contact, usually contracted when dressing the carcasses of infected animals. Humans infect other humans through fleas. When the bubonic form is complicated by pneumonia (secondary pneumonic plague), the disease is spread by airborne droplets, like influenza, and the highly contagious primary pneumonic plague occurs. Depending on the mechanism of infection, the causative agent penetrates the organism through the skin, the mucosa of the upper respiratory tract, and the conjunctiva. Carriers of the plague bacillus (in the nasopharynx) have been discovered.

The incubation period of plague is two to six days. The disease is characterized by sudden onset, chills, severe headache, agitation, and mental confusion. The body temperature rises to 40°C, and hyperemia of the face is observed. Frequently, the meninges become involved. In the bubonic form painful buboes appear on different parts of the body; symptoms of pneumonia appear in the pneumonic form. The course is generally severe. Bacteriological and serological methods are used for laboratory diagnosis.

Treatment includes the administration of streptomycin and other antibiotics. Preventive measures include epidemiological reconnaissance in areas where the disease is endemic (epizootological survey and observation of human and animal populations) and the use of live vaccines. To achieve early and emergency prophylaxis, the extermination of rodents and fleas in the wild and in dwellings is vital. In the event of an epidemic, infected persons are hospitalized, and individuals who have come in contact with them are isolated and given prophylactic treatment. Disinfection and quarantine measures are also instituted.

PLAGUE-LIKE DISEASES OF ANIMALS, a group of infectious diseases characterized by an acute course, a variety of symptoms, and high mortality (70–100 percent). The diseases included in the group (see Table 1) differ from one another in etiology, economic impact, and other aspects.

Viruses are the causative agents of most of the plague-like diseases of animals. However, camel plague and furunculosis are caused by bacteria, and crab plague is caused by a pathogenic fungus. The etiology of pike and whitefish plague has not been

Table 1. Some plague-like diseases of animals

Disease	*Animals affected*	*Principal symptoms*	*Distribution*
Rinderpest (or cattle plague)	Cattle, zebus, buffalo, sheep, goats, camels, antelopes, swine	Fever, erosions and ulcers on the buccal mucosa, conjunctivitis, rhinitis, vaginitis, miscarriages, diarrhea	Africa, Middle East; eradicated in the USSR
Classical swine fever (or hog cholera)	Swine	Fever, prostration, digestive disorders, conjunctivitis, petechial hemorrhages	Asia, America, Africa; isolated cases in the USSR
African swine fever	Swine	Fever, prostration, vomiting, convulsions, paralysis, cyanosis, hemorrhages	Africa, Spain, Portugal
African horse sickness	Horses, mules, asses, zebras; occasionally dogs	Fever, weakness, tremors, conjunctivitis, cough, cyanosis of the mucosa	Africa, Middle East
Fowl cholera	Chickens, guinea fowl, pheasants, peacocks	Fever, conjunctivitis, cyanosis of the comb and wattle, convulsions, paralysis	North Africa; sporadically in Europe, including the USSR
Newcastle disease	Chickens, guinea fowl, turkeys, pheasants, peacocks	Fever, diarrhea, discharges from the nose, and mouth, cough, paresis, paralysis	All countries
Anatipestifer infection	Ducks, less commonly geese and swans	Drowsiness, rhinitis, conjunctivitis, loss of appetite, thirst, diarrhea, inflammation of the cloaca, neurological disorders	Europe, including the USSR
Distemper	Dogs, foxes, arctic foxes, raccoons, mink, polecats, sables, jackals, wolves, cats	Fever, listlessness, loss of appetite, rhinitis, cough, conjunctivitis, vomiting, diarrhea, thirst, skin rash, pneumonia, convulsions, paralysis	Widely distributed in all countries
Camel plague	Camels, rodents, also humans	Fever, prostration, loss of appetite and rumination, miscarriages, cough, enlargement of superficial lymph nodes	Asia, Africa, America, southeastern USSR (natural reservoirs of rodent plague)
Pike plague	Pikes, rarely roach, European pike, burbot, European bream	Hemorrhagic inflammation of the buccal mucosa and gills, skin and scales, necroses, ulcers	Europe; a few cases in the USSR
Furunculosis	Salmon	Ulcerative lesions of the skin and scales, necrosis of fins	Great Britain
Whitefish plague	Whitefish (cisco and others)	Inflammation of muscles, destruction of skin and scales	Europe; a few cases in the USSR
Crab plague	Crabs	Walking on outstretched legs, convulsions	Europe, Baltic region of the USSR (several natural reservoirs)

determined, but the epizootological characteristics of these diseases suggest that they are plague-like diseases.

Plague-like diseases usually occur in epizootics affecting large numbers of animals. They occur throughout the year, strike animals of all ages, and are transmitted by food or through the air (African swine fever and camel plague are also transmissible diseases). The incubation period is brief, averaging three to 12 days; the course is acute, and the animals die soon after onset. Methods of laboratory diagnosis have been developed for almost all of the diseases. Rinderpest (or cattle plague), African swine fever, classical swine fever (or hog cholera), African horse sickness, fowl cholera, and Newcastle disease are highly contagious; control measures include mandatory notification of any outbreak of any one of these diseases, quarantine, and the slaughter of the diseased animals and the burning of the carcasses. If outbreaks of other plague-like diseases occur on a farm, restrictive measures are instituted, the diseased animals are isolated, and disinfection is carried out. Specific preventive agents (vaccines) have been developed for most of the diseases.

I. A. BAKULOV [29–762–1]

PLAGUE REVOLT, an uprising in Moscow in September 1771 caused by an epidemic of plague. The immediate crisis was aggravated by the discontent of many Muscovites with unemployment, famine brought on by the closing of factories as a quarantine measure, and an absence of medical help. The direct cause of the revolt was the attempt by Ambrosius, the archbishop of Moscow, to prevent crowds from gathering near the miracle-working icon at the Varvarka Gate of Kitai-Gorod; he thereby hoped to prevent the spread of the plague.

On September 15, responding to an alarm, a crowd of thousands that included landless household serfs, peasants on quitrent, tradesmen, and laborers pushed back the troops at the Varvarka Gate and set out for the Kremlin, where the city's rulers were hiding. On the following day the mob stormed the Don Monastery and killed Ambrosius, who had taken refuge there; it then began destroying the quarantine barriers. Troops under G. G. Orlov were sent to crush the revolt, which was disorganized in character.

The Plague Revolt was cruelly suppressed. More than 300 of the participants were put on trial, of whom four were hanged (the merchant I. Dmitriev and the household serfs V. Andreev, F. Deianov, and A. Leont'ev) and 173 flogged and sentenced to hard labor. At the same time, the government was forced to take more effective measures against the plague and to provide assistance to the urban populace in the form of jobs and food. The Plague Revolt provoked disturbances among the peasants in the vicinity of Moscow and in the neighboring districts of Moscow Province.

PLASTER AND STUCCO (in Russian, *shtukaturka*), hardened finishing layers formed by a mortar applied to the surfaces of structural members and parts of buildings and other structures.

Various types of plaster and stucco are distinguished in modern construction: conventional types designed to smooth the surfaces of walls and partitions, prepare them for final treatment (painting and wallpapering), and protect against atmospheric effects (for example, in finishing the facades of buildings); special types, such as for fire protection, sound absorption, and X-ray protection, which are used as insulating and screening layers; and decorative types, used to enhance the aesthetic expressiveness of buildings and other structures. Different types of plaster and stucco are used depending on the type of building or other structure and the requirements for the quality of finish on surfaces: simple types—for temporary buildings and warehouses and where wooden walls will be subsequently tiled; improved types—in large-scale residential and public buildings; and high-grade types—in buildings constructed to individual designs.

Plaster and stucco finishes may be applied as a wet solution directly on a surface, or the surface may be finished with large, prefabricated sheets and slabs. Plaster and stucco must be strong, with an even, smooth surface and without traces of the applicator or cracks.

G. I. VERSTIN [29–1498–5]

PLASTERING AND STUCCOING, the finishing of surfaces of structural members and other parts of buildings and other structures (exterior and interior walls, ceilings, partitions, and the like) with a plaster or stucco mortar; the mortar is applied wet to the application surfaces. Because the work is very labor-intensive, in modern industrial construction plastering has in large part been replaced by the facing of surfaces with large dry-plaster sheets and other efficient prefabricated finishing materials.

In wet plastering, the composition of the plaster mortar applied depends on the purpose of the plaster, the material of the surfaces being plastered, and the conditions under which the buildings will be used. For example, lime mortars are used to plaster interior stone walls of rooms with normal humidity (up to 60 percent), and lime-gypsum mortars are used for wood partitions. Cement and lime-cement mortars are used in areas with increased humidity, such as bathrooms, laundries, and bathhouses.

Plastering mortars are usually manufactured at centrally located plants, chiefly in the form of dry mixes that are delivered to construction sites. Mortar-mixing units and mobile plastering stations mounted on motor vehicle trailers are used to prepare the mortars to the required composition at the sites.

In most cases the application of wet plaster is mechanized; plastering machines supply and apply the mortar by means of pumps. Hand plastering is reserved for small jobs and areas difficult to reach. The mortar is supplied through rubber hoses or metal pipes. The type and diameter of the feed line and the capacity of the pump depend on the number of stories in the building, the amount of wet plaster, and the distance over which the mortar must be delivered (up to 200 m horizontally and 40 m vertically). Special nozzles are usually used to apply the mortar to the surface being plastered. The mortar is usually applied in three layers. The first two layers are required for all types of plaster and stucco; the third is required for improved and high-grade types. Electric and pneumatic finishers and power tools are used for the final dressing of the top layer.

In areas where humidity under operating conditions will not exceed 60 percent, surfaces are finished with dry-plaster (gypsum, gympsum-fiber, and wood-fiber) sheets. Gypsum facing sheets, manufactured from construction-grade gypsum with mineral or organic additives and covered with cardboard on two sides, are most frequently used. Sheets produced in the USSR (1978) have lengths of 250, 270, 290, and 330 cm; widths of 120 and 130 cm; and thicknesses of 1.0 and 1.2 cm. Facing sheets must be correctly shaped and undamaged at the corners and edges, and the face side must not show seams where the cardboard is glued. The grading, laying out, and cutting of sheets to dimensions is usually done at centralized workshops at the construction site. Sheets are cemented to rock or concrete surfaces with gypsum glue, gypsum foam, and other mastics; they are attached to wood surfaces with galvanized nails or wood screws. Before wallpapering, the seams between dry-plaster sheets are filled with gypsum mastic.

PLUG-AND-SOCKET CONNECTION, a detachable device for the quick connection and disconnection of electric circuits. Electric contacts in the form of metal jacks and of metal pins or blades that are inserted into the jacks constitute the basis of a plug-and-socket connection. The number of contacts may range from one to several hundred; in the latter case, the device is often called a plug-and-socket connector. The simplest type of plug-and-socket connection is the plug and socket used to connect portable household or industrial appliances to an outside power supply.

[29–1471–1]

POETIC EDDA (also *Saemund's Edda, Elder Edda*, or simply *Edda*), a collection of ancient Icelandic lays. The *Poetic Edda* survives in a 13th-century manuscript; its compiler is unknown. The lays long existed only in oral form, and the date of their composition remains in dispute. Several have been preserved in other ancient manuscripts.

Some of the lays are cast in the form of prophecies, apothegms, or theatrical presentations based on mythology; others are simple narratives. The mythological lays, of which *Völuspa* (The Seeress' Prophecy) is the most important, are the only source of their kind on pagan mythology. Many of the heroic lays derive from south Germanic folk legends. Although the lays show the influence of different periods, their ideology and style indicate that the *Poetic Edda* antedates the ancient Germanic epics.

PORTLAND BLAST-FURNACE SLAG CEMENT, a cement produced by grinding portland cement clinker together with pellets of blast-furnace slag (30–60 percent of the total weight) and a small amount of gypsum. It differs from ordinary portland cement by a slower increase in strength in the initial hardening period and an increased water resistance. It is used mainly for manufacturing precast reinforced-concrete structures and items prepared with steam curing as well as for laying concrete in hydraulic engineering installations. [29–1274–1]

POSTAGE METER, a machine designed to imprint a dated postmark on written correspondence, such as letters and postcards, and to cancel the symbols of postage payment or to cancel regular postage stamps. The imprinted postmark contains the name of the communications enterprise and the date and time of cancellation; the stamp cancellation consists of three wavy lines.

A postage meter operates in the following manner. A packet of letters or postcards is sorted so that the addresses appear on the same side and the stamps are located in the same position in the upper right corner; the packet is then transferred from a storage unit to a separator. From the separator each letter is individually guided across conveyor rollers to the device that prints the postmark, whose single-cycle mechanism is set in motion by an arm engaged by the forward edge of the moving letter. The cancelled letters are ejected by a blade wheel into the next storage unit.

The most widely used postage meters in the USSR are the ShM-4A for large postal enterprises (designed for prolonged, continuous operation) and the ShMN-2 for regional postal centers and communications offices. The best-known foreign postage meters are made by the American firm of Pitney-Bowes, Inc., the British company Universal Postal Frankers, and the French company SECAP. Postage meters can process from 12,000 to 45,000 letters per hour. K. V. BOROZDIN [29–1470–2]

PRINT AND LETTERING, the graphic form of the symbols of an alphabetic writing system. Depending on the reproduction technique used, a distinction is made between handwriting, which is produced with a pen or other implement on a soft material, such as papyrus, parchment, or paper; lettering applied by hand with a brush or other implement on signs, vases, fabric samples, original bookbindings, book covers, title pages, and other elements of publications; engraved lettering, which is cut or stamped in wood, metal, stone, or some other hard material and used for inscriptions on monuments, architectural structures, or engravings; and print, which consists of individual letters and other elements and which is designed for the manual or mechanized composition of texts to be reproduced by printing, chiefly on paper. In the narrow sense, a full set of print characters designed for composition is called a typeface.

Depending on the intended use, typefaces are subdivided into text faces—for text composition; display faces—for the composition of covers, title pages, and headings; and decorative faces—for the composition of small printed items, such as diplomas, blank forms, labels, and announcements.

Figure 1. Graphic features of the principal type families: (a) Literary (formerly, Latin), Bannikov, Garamond, (b) Baskerville, (c) New Standard, Elizaveta, Bodoni, (d) Academic, School, Bazhanov, (e) Telingater, (f) Newspaper Square Serif, Memphis, (g) Journal Sans Serif, Univers

Typefaces may be divided into seven groups depending on weight (the ratio of the width of the thick strokes to that of the thin strokes in the letters) and on the presence and shape of serifs (Figure 1). A special group comprises typefaces that, because of their form, cannot be included in the groups in Figure 1, including scripts and faces that imitate the typefaces of typewriters. Depending on the form, which is determined mainly by the letters' inclination, width (the ratio of the thickness of a stroke to the width of the counter), and weight, typefaces may be upright, cursive, or oblique; normal, condensed, or expanded; and light, medium, or bold. Typefaces of a given form are divided into different type sizes; typefaces that are different in size and form but quite similar in overall design are combined into groups, called type families. Every type family has a name, for example, Elizaveta, Bannikov, and School. The variety of type families used in printing houses in the USSR is regulated by state standards.

The design of the first typefaces was based on handwriting; examples are the Russian Manuscript Poluustav (Figure 2,a), based on Russian handwriting, and Gothic (Figure 2,b), based on Latin handwriting. The primary source of modern Russian Cyrillic typefaces is the Russian Civil typeface (Figure 2,c), which was approved by Peter the Great in 1708. The original source of modern Latin alphabet type is the Roman form (Figure 2,d), which appeared in the late 15th century during the Renaissance. Some type families that appeared as early as the beginning of the 20th century are still used in printing houses in the USSR: Literary (formerly, Latin; Figure 2,e), Elizaveta (Figure 2,f), and Academic (Figure 2,g).

The type families that have been developed in the USSR since the late 1940's include New Standard (Figure 2,h), Bannikov (Figure 2,i), and Lazurskii (Figure 2,l), for publications of literature and art books (all based on the Civil typeface of the Petrine period and typefaces of the Renaissance); School (Figure 2,j), for textbooks in primary and secondary schools and children's publications; Modern Newspaper, for newspapers; Journal Sans Serif (Figure 2,k), for periodicals; and Rerberg (Figure 2,m), Telingater Decorative (Figure 2,n), Bazhanov (Figure 2,o), and Kuzanian (Figure 2,p), used as display type (all based on the hand letters of contemporary artists). Editions of political, scholarly, and children's publications, works of fiction, and textbooks are often composed in a single typeface (usually a well-established face of classic design).

Many designs of modern Latin alphabet typefaces that are used extensively in foreign countries were modeled on classical designs, such as Garamond (France, 1530's; Figure 2,s), Caslon

(Great Britain, early 18th century), Baskerville (Great Britain, mid-18th century; Figure 2,q), and Bodoni (Italy, early 19th century; Figure 2,r). Original models of modern Latin alphabet typefaces include Egyptian faces (with very little contrast between

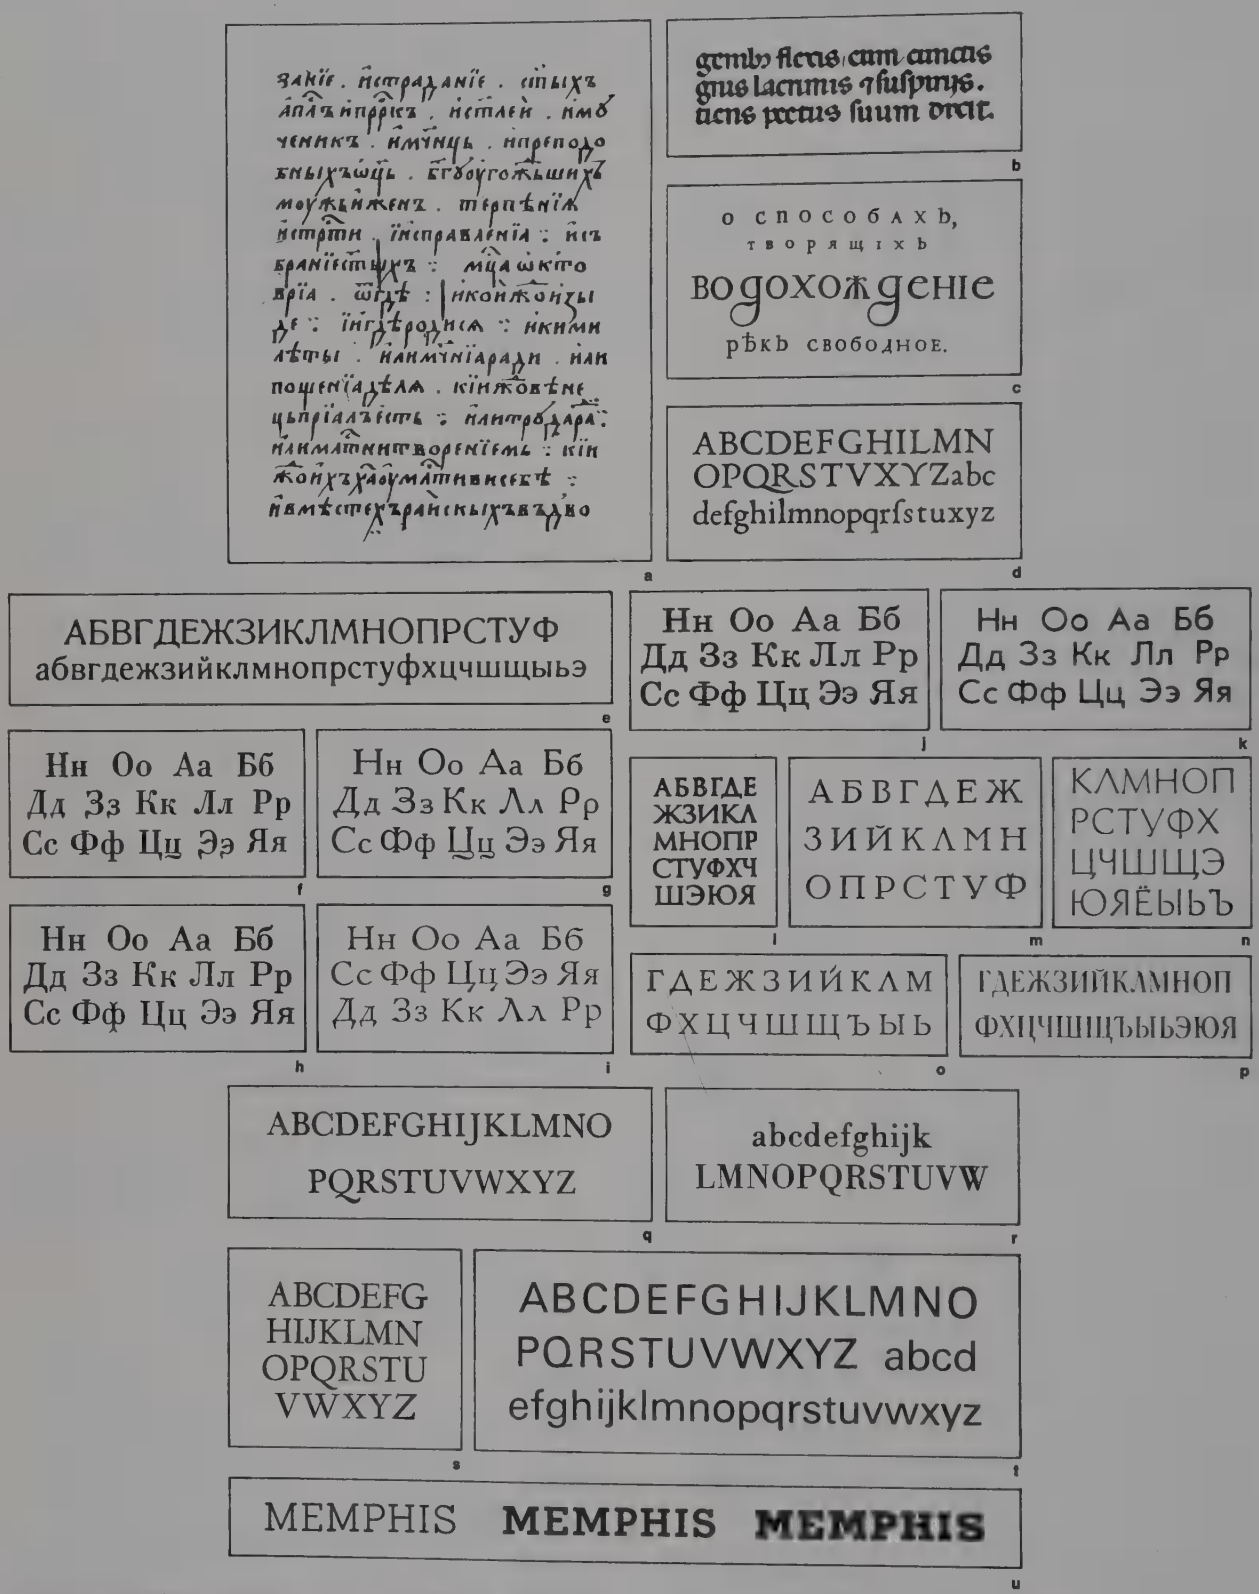

Figure 2. Samples of typefaces and type families: (a–d) historical, (e–p) modern Russian Cyrillic, (q–u) modern Latin alphabet; (a) Manuscript Poluustav, (b) Gothic, (c) Civil, (d) Roman, (e) Literary, (f) Elizaveta, (g) Academic, (h) New Standard, (i) Bannikov, (j) School, (k) Journal Sans Serif, (l) Lazurskii, (m) Rerberg, (n) Telingater Decorative, (o) Bazhanov, (p) Kuzanian, (q) Baskerville, (r) Bodoni, (s) Garamond, (t) Univers, (u) Memphis

thick and thin strokes and rectangular or slab-shaped serifs), (Figure 2,u) and Beton, and sans-serif faces, such as Futura, Gill Sans, and Univers (Figure 2,t).

PRIVATE ACCUSATION, a form of criminal prosecution initiated on the complaint of the victim or his representative and subject to termination in the event that the victim is reconciled with the accused (*see* PRIVATE-PUBLIC ACCUSATION). The accusation is supported by the victim himself; in this sense it is considered private.

In Soviet law, cases of crimes involving relatively little social danger are prosecuted by private accusation. Such crimes include defamation, insult, and the infliction of light bodily injury; complete lists of these crimes are provided in the codes of criminal procedure of the Union republics.

Where private accusation is involved, the case is initiated by a judge if the measures he has taken to effect a reconciliation between the victim and the accused have been unsuccessful. Reconciliation is possible until the court leaves for the conference room to decide on a verdict and sentence; under the codes of criminal procedure of the Lithuanian and Estonian soviet socialist republics, reconciliation is possible until the sentence enters into force.

In cases initiated on the complaint of the legal representative of a minor or of a person who is unable to defend his own interests because of physical or mental handicap, the proceedings may be terminated by reconciliation only if the victim's legal representative gives his consent.

In certain instances—if a case has special social significance or if a victim is not in a position to defend his rights and legal interests owing to, for example, his helpless condition or his dependence on the accused—the procurator has the right to initiate proceedings even in the absence of a complaint by the victim. A case initiated by a procurator is not subject to termination in the event that the victim and the accused are reconciled; moreover, the victim is deprived of the right to support the accusation. If a case initiated by a procurator is tried in the absence of the procurator, however, then according to the codes of criminal procedure of some of the Union republics, the victim retains the right to support the accusation.

A procurator may also at any time enter a case initiated by a judge and support the accusation if such action is required for the protection of state or social interests. In such instances, the case may not be terminated in the event that the victim is reconciled with the accused; in accordance with the codes of criminal procedure of most of the Union republics, however, the victim retains the right to support the accusation.

Under the legislation of the RSFSR and of the Moldavian, Tadzhik, Armenian, Turkmen, Latvian, and Lithuanian soviet socialist republics, a case initiated by a judge is not subject to termination in the event of the reconciliation of the parties if a preliminary investigation or inquiry has been conducted. [29–80–10]

PRIVATE LABOR. (1) Labor on discrete small units, where production is closed: that is, directed toward the satisfaction of the producer's own needs, as in a natural economy (*see* SMALL HOLDING). Private labor of this type is possible only if the division of labor does not go beyond the bounds of family cooperation, if the land is parceled out, and if the other means of production are scattered. As Marx noted, "This method of production is compatible only with the narrow original boundaries of production and society" (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 23, p. 771). Independent private labor on separate small units eventually leads to the development of private ownership. In examining the disintegration of communal property, Marx wrote that "the most essential point is the parceling of labor, the source of private appropriation" (*ibid.*, vol. 19, p. 419).

As productive forces developed, small holdings were increasingly drawn into the social division of labor and cooperation of labor, and the private labor characteristic of the small holding assumed a form typical of commodity production. Even under these conditions, however, private labor of the kind associated with the small holding is anomalous and is found only on patriarchal, single-family farms.

(2) A particular historical form of labor inherent in spontaneous commodity production, a form assumed by the production units making up a system of the social division of labor when private ownership is dominant. The social division of labor is a necessary but insufficient condition for the emergence and existence of this form of private labor, which is found only where the social cooperation of labor is spontaneous and relations between the various primary elements in the division of labor assume the character of value relations. "Only such products can become commodities with regard to each other as result from different kinds of labor, each kind being carried on independently and for the account of private individuals" (K. Marx, *ibid.*, vol. 23, p. 51).

In the spontaneous cooperation of labor, under which labor inevitably becomes private, the social contact between private producers comes about only through, and within the framework of, the exchange of the products of labor, thereby generating a system of indirect relations, involving the reduction of labor through value. Money is the most highly developed form of value; in it the essential lack of independence of private labor is manifested. In any equivalent form of exchange, consequently, "the labor of private individuals takes the form of its opposite, labor directly social in its form" (*ibid.*, p. 68).

The spontaneous cooperation of labor also gives rise to commodity fetishism, in which the relations between commodities (the results of private labor) disguise the social relations between people.

As the planned cooperation of labor progresses, the economic isolation of private acts of labor decreases. Even under capitalism there may be social contacts between the producing elements not only in the marketplace but also in economic programming and in interrelationships with the bourgeois state in the area of taxes, prices, and other forms of economic regulation. As long as capitalist ownership is dominant, the contradiction between the social and private nature of labor remains the chief cause of all antagonisms in capitalism, including its basic contradiction—that between the social character of production and the private, capitalist form of appropriation.

In a planned socialist economy, labor loses the characteristics of private labor: the production units no longer labor independently of one another, nor do they make contact with one another only in the exchange of commodities. Labor ceases to be the private affair of independent producers and increasingly becomes direct social labor; under communism all labor will be direct social labor in the fullest sense of the term. Socialism still retains some features of private labor: workers and the production units are still relatively isolated, and the indirect reduction of labor through the operation of the law of value remains. These features will disappear as socialism is transformed into communism.

PRIVATE LAW, in the bourgeois theory of law, the norms regulating certain relations, including property relations, between private individuals and also governing relations in which the state

and its agencies act not as bearers of public authority but as parties to contractual relations. Private law includes the norms of civil, commercial, and family law.

Whereas public law governs relationships of authority and subordination, private law deals with the relations of formally equal persons. Its subjects enjoy considerable economic and legal autonomy, and the protection of private interests is exercised only on the initiative of the interested persons themselves.

Bourgeois jurists treat private law as "a manifestation of the freedom of the individual" and of purportedly equal possibilities for all. The division of law into private and public, however, reflects the conflict between private and public interests in societies that are marked by antagonism among classes. As K. Marx and F. Engels noted, "Private law develops simultaneously with private property out of the disintegration of the natural community" (*Soch.*, 2nd ed., vol. 3, p. 63). Private law is based on the law of private property, which evolved under Roman law and is fully developed and protected by capitalism; under capitalism the law of private property is declared to be "holy and inviolable."

In the modern era, the development of state monopoly capitalism and the increasing interference of the bourgeois state in the capitalist economy have led to a blurring of the sharp distinction between public and private law as private law is "made public."

The socialist legal system does not distinguish between public and private law. [29–82–1]

PRIVATE-PUBLIC ACCUSATION, a form of criminal prosecution initiated on the complaint of the victim or his representative. In contrast to cases prosecuted by private accusation, such a case is not subject to termination in the event that the victim is reconciled with the accused or renounces the complaint (*see* PRIVATE ACCUSATION).

In Soviet law, cases of rape without aggravating circumstances and of the violation of authors' or inventors' rights are prosecuted only by private-public accusation. Such cases are investigated and tried under the general procedure for criminal trials, as established in the codes of criminal procedure. The victim himself does not support the accusation since a procurator takes part in the court hearing; thus, it is a private accusation that is publicly supported.

In exceptional instances—if a case involving the violation of authors' or inventors' rights has special social significance or if a victim is not in a position to defend his rights and legal interests owing to, for example, his helpless condition or his dependence on the accused—the procurator has the right to initiate proceedings even in the absence of a complaint by the victim. [29–82–3]

PROSE EDDA (also *Snorri's Edda, Younger Edda*), a work written by the Icelandic prose writer and poet Snorri Sturluson between 1222 and 1225. The *Prose Edda* is divided into a prologue and three parts. Many of the pagan myths recounted in the work appear in no other source. In one section Snorri explains the significance of the kennings (metaphorical expressions) and *heiti* (poetic synonyms) used in skaldic poetry and illustrates his explanations with examples from the works of the skalds. The *Prose Edda* also contains an original narrative poem with a prose commentary in a style reminiscent of a scholastic treatise.

PUBLICATION

In Russian translation:

Mladshaia Edda. Afterward by M. I. Steblin-Kamenskii. Leningrad, 1970. (Contains bibliography.) [29–1678–3]

PRUNE, a dried plum of the varieties Vengerka Ital'ianskaia, Vengerka Domashniaia, and others. The variety Vengerka Ital'ianskaia yields the best prunes.

Only fleshy ripe plums are suitable for drying. The stone must separate readily from the flesh, and the pulp must contain no less than 10 percent sugar and no more than 1.2 percent acid. The plums are blanched to accelerate drying, remove the waxy coating, and obtain cracks in the skin. Vengerka Ital'ianskaia plums are blanched for 20 to 30 seconds; plums of other varieties are blanched for one to 1½ minutes. The plums are then cooled under running water and placed in steam dryers for eight to ten hours at a temperature of 80°C. Toward the end of drying the temperature is lowered to 60°C. After cooling and sorting, the prunes are immersed in boiling water for 1½ to two minutes to obtain a shine. They are then treated with glycerin (5 kg per ton of prunes).

There are three grades of commercial prune varieties. Prunes must be black, soft, and tart. The yield of prunes from fresh plums is 20 to 22 percent. [29–301–2]

PRUNELLA, a genus of perennial herbs of the family Labiatae. The opposite leaves range from entire to pinnatipartite. The flowers are in false whorls that form a dense spicate inflorescence; the corolla has an arched upper lip. The fruit consists of four nutlike lobes. There are five to seven species, distributed in temperate and subtropical zones of the northern hemisphere. The USSR has four species. Self-heal (*P. vulgaris*), with tiny violet flowers, is common along roads and in glades, forest margins, sparse forests, meadows, fields, and wastelands. *P. grandiflora*, with large violet or reddish flowers, occurs in the European USSR, mainly in the south, and in the Caucasus; it is cultivated as an ornamental. [29–262–5]

PSITHYRUS, a genus of bees that are closely related to bumblebees (family Bombidae) and that parasitize their nests. Psithyri females deposit their eggs in the nests of the bumblebee hosts, which rear the young of the parasitic bees as their own. Adult psithyri are also accepted by the bumblebees as their own and are not driven from the nests. Psithyri greatly resemble their hosts in appearance; the female psithyri can only be distinguished from female bumblebees by the absence of pollen combs and pollen baskets on their legs. [29–1313–2]

PUCK, in ice hockey, a black, hard-rubber disk with flat top and bottom surfaces. It is 76.2 mm in diameter, 25.4 mm thick, and weighs 140–170 g. The sides are lightly scored. [29–808–3]

PULLEY, a rotating part of a belt drive or a cable transmission, made in the form of a wheel around which a flexible link passes. Drive pulleys and driven pulleys, which transmit torque, are fastened to shafts by means of, for example, key or spline joints. Pulleys that do not transmit torque, such as idler and tension pulleys, turn freely on shafts or axles. Pulleys with grooved surfaces are sometimes called sheaves.

Pulleys are available in a wide variety of designs. Pulleys of small diameter are manufactured in one solid piece (Figure 1,a). Pulleys of medium or large diameter (Figure 1,b) have a hub (1) and a rim (2) connected by a web (3) or by arms. Large pulleys are sometimes produced in two halves, which are bolted together. Pulleys may be made of cast iron, steel (Figure 1,c), a light alloy, plastic, or—in some cases—wood.

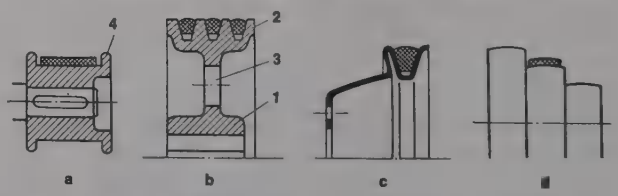

Figure 1. Pulleys: (a) a one-piece pulley, (b) a pulley with a hub and rim, (c) a pressed-steel pulley, (d) a step pulley

Flat-belt pulleys (Figure 1,a) have a cylindrical or crowned peripheral surface to prevent the belt from being thrown off; flanges (4) are sometimes used for the same purpose. V-belt pulleys for single-belt or multiple-belt drives have grooves with a trapezoidal cross section (Figure 1,b). Round-belt pulleys have a groove with a rounded bottom. Timing-belt pulleys have flanges and axial grooves for the teeth of the timing belt. Step pulleys (Figure 1,d) are used in drives in which the transmission ratio is adjusted by shifting the belt from one step to another. Double-cone pulleys in continuously variable transmissions with a wide V belt are produced with one or two spring-loaded movable cones; the displacement of one or both cones is forced.

N. IA. NIBERG [29–1254–3]

PUREBREEDING (also pedigree breeding), one of the main methods of breeding agricultural animals, in which the progeny are produced by mating animals of the same breed. The concept of purebreeding emerged in the 16th and 17th centuries, when people consciously isolated valuable strains for breeding without mixing with less valuable strains.

The goals of purebreeding are to limit variability within a breed; to impart to a particular breed uniformity in conformation, productivity, and hereditary factors; to create and maintain a particular breed, ensuring not only the retention in the animals of economically valuable qualities inherent to the breed but also the breed's further improvement in a given direction; and, finally, to impart hereditary stability to the breed.

Purebreeding is used to produce breeding lines with more flexible heritability and greater variability than the native stock; it is also used in breeding some primitive strains, which are less productive but distinguished by high adaptability to local climatic and economic conditions or by high resistance to local diseases. Purebreeding is usually erroneously identified with inbreeding or breeding hybrids (based on the same principles as purebreeding), produced by crossing different breeds and meeting the requirements of the given breed.

[29–644–3]

PURE CULTURE, a culture containing cells of a single species of microorganism.

The most reliable way of isolating a pure culture is from a single cell of a population. For yeast and microscopic fungi, this is accomplished by Lindner's drop technique. Drops from a cellular suspension of yeast or fungi spores (conidia) are transferred to a cover glass, or cover slip. The cover glass is then placed over a cavity slide. Microscopic techniques are used to find a drop containing a single cell, and the drop is then transferred, using sterile procedures, to a culture medium. Pure, single-cell bacterial cultures are isolated with the aid of a micromanipulator or thin capillaries (B. V. Perfil'ev's microselector).

The isolation of pure cultures is necessary in the classification and study of the variability of microorganisms and in the production of vaccines. It is also used in the microbiological industry for the preparation of enzymes, antibiotics, vitamins, steroid hormones, and other preparations. [29–645–3]

PURE LINE, the homogenous generations of repeatedly self-pollinating plants or self-fertilizing animals, in which most genes are homozygous. The term was introduced in 1903 by the Danish geneticist W. Johannsen, who proved by experimentation on legumes that pure lines exhibit analogous phenotypes under identical conditions.

Pure lines are obtained from a single ancestor and are maintained by self-pollinization and selection. Individuals in pure lines repeat over several generations the same genetically fixed traits. Pure lines are important in agriculture inasmuch as they are the main structural elements of plant varieties. Hybridization of two pure lines often results in heterosis in the first hybrid generation; certain hybrid varieties of corn are obtained in this way.

The term "pure line" is sometimes incorrectly applied to inbred lines, which are the progeny of animals or cross-pollinated plants obtained from a single pair of ancestors and maintained over a number of generations by constant crossing of related individuals and by selection. Such lines are almost always used in genetic research on higher organisms. For example, "pure line" laboratory mice are used to study carcinogenesis and cancer treatment. I. I. TOLSTORUKOV [29–637–5]

PURE METAL, a metal with a low admixture content. Depending on the degree of purity, the following types of pure metals are distinguished: high-purity metals (99.90–99.99 percent pure); superpurity, or chemically pure, metals (99.99–99.999 percent pure); and ultrapure metals (more than 99.999 percent pure). [29–645–4]

PURE STATE. A pure state of a quantum-mechanical system is a state that is characterized by specifying the complete set of possible values of the dynamic variables that define the state of the system. A pure state is described by the wave function of the dynamic variables and is a basic concept of quantum mechanics. A superposition of wave functions—that is, the sum of such functions with arbitrary complex coefficients—also describes a pure state of a system. A pure state is often simply called a quantum state, although there is a more general case, namely the mixed state, in quantum mechanics. (*See* MIXED STATE.) [29–642–3]

PURGATORY, according to Catholic dogma, a place where the souls of dead sinners can be cleansed of sins committed in life. The cleansing is supposedly accomplished through the sinner's enduring various trials; it is also accomplished through the prayers and good works of the relatives of the deceased, primarily through their monetary contributions to the church. The doctrine of purgatory was adopted by the Council of Florence (1438–45) and was confirmed in 1562 by the Council of Trent. [29–641–1]

PURGE OF THE PARTY (Russian, *chistka partii*), verification of the observance of the Rules of the Communist Party and the norms of communist morality by members of the party in order to increase members' political activity and eliminate socially alien elements and persons who violate party and state discipline from the party ranks. V. I. Lenin pointed out that "careerists and charlatans . . . inevitably do all they can to insinuate themselves into the ranks of the ruling party" (*Poln. sobr. soch.*, 5th ed., vol. 41, p. 30). In the period of the dictatorship of the proletariat, therefore, the party resorted several times to systematic purges and examinations of the party ranks.

The first party purge was a general purge; that is, it affected all party organizations. It was conducted in accordance with a resolution adopted by the Tenth Congress of the RCP(B), which was held in 1921, in response to the revival of capitalist elements in the country and the appearance of capitalist agents in the party during the transition to the New Economic Policy. To carry out the purge, the Politburo of the Central Committee formed a central commission, and local party bodies formed city and raion commissions, to check on the work of all party organizations and members. The purge was conducted at open party meetings with the participation of broad masses of nonparty workers, whose involvement Lenin especially valued. As a result of the purge, 24.1 percent of the party's members were expelled.

A purge of nonindustrial party organizations, which made up 25 percent of the party membership, was carried out in 1925 in accordance with a resolution adopted by the Thirteenth Congress of the RCP(B), which was held in 1924. Six percent of the party's members were expelled. A partial examination of rural party organizations was carried out in 1926 with a view to cleansing the party of kulak elements.

The second general purge was called for by the Sixteenth Party Conference, which was held in 1929. It took place in 1929 and 1930, during a period of a full-scale offensive against urban and rural capitalist elements and of an intensification of the class struggle; 7.8 percent of the party's members were expelled.

The third general purge was carried out in implementation of a resolution of the United Plenum of the Central Committee and the Central Control Commission of the ACP(B) of January 1933. The purge affected 25 territorial party organizations; 18.3 percent of the members were expelled. The remaining 17 territorial party organizations were purged during the verification and exchange of party documents carried out in 1935 and 1936.

The purges produced beneficial results and increased the prestige of Communists among the masses, although some mistakes were committed, such as expulsion for "passivity." These mistakes were subsequently corrected by the Central Control Commission and the Central Committee of the ACP(B). In view of the victory of socialism and the liquidation of capitalist elements,

the Eighteenth Congress of the ACP(B) abolished the party purge in the belief that the party can cleanse its ranks in a routine manner of persons who violate the party program and the Rules and who are unworthy of the lofty name of Communist.

[29–641–2]

PYGOPODIDAE, a family of reptiles of the order Sauria. The snakelike body reaches 80 cm in length. The front extremities are not developed, and the back extremities resemble small fins covered with scales; they are practically unnoticeable in some species. The tail is very long. The eyes are small, with vertical pupils. The eyelids have fused into a transparent membrane.

The Pygopodidae embrace eight genera, with approximately 30 species. The lizards are distributed mainly in Australia, as well as in New Guinea and neighboring islands. They are primarily nocturnal and usually live in tall grasses. They feed on insects and other invertebrates. [29–528–5]

QUADRIPARTITE AGREEMENT ON WEST BERLIN, an agreement signed on Sept. 3, 1971, in West Berlin in the former seat of the Control Council by the Soviet ambassador to the German Democratic Republic (GDR) and the American, French, and British ambassadors to the Federal Republic of Germany (FRG). It went into effect after the Final Quadripartite Protocol was signed on June 3, 1972, by the secretary of state of the USA and the foreign ministers of Great Britain, France, and the USSR. The agreement was a result of talks held in 1970 and 1971 between the ambassadors of the four powers at the initiative of the USSR.

The agreement is based on a recognition of the existing political realities and territorial boundaries in Europe. A key clause affirms that the western sectors of Berlin "continue not to be a constituent part of the FRG and not to be governed by it." The agreement regulates the flow of civilian persons and goods between West Berlin and the FRG by way of the GDR in a manner that recognizes the GDR's prerogatives as a sovereign state; traffic identified as through, or transit, traffic is to be treated according to international practice. The agreement states that residents of West Berlin may visit East Berlin and other parts of the GDR under conditions comparable to those applying to other foreign visitors.

In the agreement the Western powers maintain their rights and responsibilities relating to the representation abroad of the interests of West Berlin and its residents. However, provided that matters of security and status are not affected, the FRG may perform consular services for the residents of West Berlin and may act for them in the international arena in other strictly limited spheres. The agreement authorizes the establishment of a Soviet consulate general in West Berlin and the opening of an office for Soviet foreign trade associations. Other Soviet institutions are also permitted to establish facilities.

The Quadripartite Agreement on West Berlin constitutes a major step toward normalizing the position of West Berlin, which has for many years been a source of international tension. The agreement promotes détente in Europe and facilitates an overall improvement in the international situation.

QUARTER-TONE SYSTEM, a tonal system based on the division of the octave into 24 equal intervals of ■ quarter tone instead of the usual 12 halftones. Theoretical work on the quarter-tone system began in 1910, and several composers have used the system in their works. The most prominent exponent of the quarter-tone system was the Czech composer A. Hába. In the USSR, A. M. Avraamov and G. M. Rimskii-Korsakov experimented with the quarter-tone system.

QUARTER-WAVE STUB (also quarter-wave line), a section of a microwave transmission line that is a quarter-wavelength long at the fundamental frequency being transmitted. The input impedance of a quarter-wave stub is inversely proportional to its load impedance. This property of quarter-wave stubs makes it possible to use such stubs in many microwave devices, such as quarter-wave transformers and antenna switches. [29–355–3]

QUATERNARY GEOLOGY, the branch of geology that studies the Quaternary, or Anthropogenic, system and the corresponding period of earth history [*see* ANTHROPOGENIC SYSTEM (PERIOD)]. The Quaternary period covers the period directly preceding the modern age, and therefore Quaternary geology is closely linked with the scientific disciplines that study the present-day face of the earth and the existing organic world: geomorphology, climatology, soil science, zoology, botany, archaeology, engineering geology, and other disciplines.

Quaternary geology has become an independent scientific discipline owing to a number of special characteristics of its object and methods of investigation and the problems it resolves. In terms of length (600,000 to 3.5 million years according to different estimates), the Quaternary period is not commensurate with other periods of earth history. However, it has been characterized by profound changes in the entire physicogeographic appearance of the earth's surface as a result of global climatic changes, expressed in the development of several periods of continental glaciation on one-fourth of the land area. The Anthropogenic (or Quaternary) period is the period during which the human race and human society have formed and developed. Information about the early stages of society has been obtained primarily from the remains of material culture.

Quaternary deposits are characterized by certain specific features: universal distribution both on land and in the seas; the predominance of continental deposits on the continents; relatively thin, gently bedded accumulations; loose deposits; and good preservation. Evolutionary changes in the organic world during this short segment of geological history have been minor, which has limited the possibility of using the stratigraphic method to delineate Quaternary beds. Consequently, detailed stratigraphic subdivisions of the Quaternary system are based on climatic data. In addition to the methods of investigation used in geology as a whole, Quaternary geology uses a number of special methods and techniques, including radiocarbon dating, thermoluminescent dating, cryolithological dating, paleomagnetic dating, the geochronological method of studying banded clays, diatom analysis, and paleoanthropological and archaeological methods. Geomorphological methods and palynological methods (pollen analysis) are especially important.

The foundations of Quaternary geology were laid in the second half of the 19th century and the early 20th century by Russian and Soviet researchers, including P. A Kropotkin, A. P. Pavlov, V. A. Obruchev. G. F. Mirchink, and S. A. Iakovlev, and by a number of foreign scientists, including A. Penck, E. Brückner, P. Woldstedt, R. Flint, and F. Zeuner.

Quaternary geology became an independent scientific discipline in the 1920's and 1930's, when groups of specialists working on certain problems of Quaternary geology emerged in the USSR and in such foreign countries as Germany, Sweden, Finland, and

the United States. In the USSR, various higher educational institutions began offering courses in Quaternary geology, the Commission for the Study of the Quaternary Period of the Academy of Sciences of the USSR was established (1927), and a methodology for the geological mapping of Quaternary beds was developed.

The International Union for Quaternary Research (INQUA) was founded in 1932.

The principal areas of study in Quaternary geology include biostratigraphy (V. I. Gromov, G. I. Goretskii, K. V. Nikiforova), climatic stratigraphy (S. A. Iakovlev, A. I. Moskvitin, I. I. Krasnov), lithogenesis (E. V. Shantser), geomorphology (A. A. Aseev), and paleogeography (I. P. Gerasimov, K. K. Markov). In addition, problems of neotectonics (N. I. Nikolaev) and "young" volcanism (E. E. Milanovskii) are under study, and methods of mapping Quaternary beds are being developed (G. S. Ganeshin).

The most important research in Quaternary geology is being conducted at the Geological Institute and the Institute of Geography of the Academy of Sciences of the USSR in Moscow, the Institute of Geology and Geophysics of the Siberian Division of the Academy of Sciences of the USSR in Novosibirsk, the All-Union Geological Research Institute in Leningrad, and various research institutes in the Baltic republics, Byelorussia, and the Ukraine. Various problems of Quaternary geology are discussed at INQUA congresses and commissions and at international geological and geographic congresses. All-Union and regional meetings are held regularly in the USSR. The Interdepartmental Stratigraphic Committee established a permanent commission on the Quaternary system in 1956 to deal with stratigraphic problems.

Problems of Quaternary geology are discussed in numerous periodical publications, including *Biulleten' kommissii po izucheniiu chetvertichnogo perioda* (Bulletin of the Commission for the Study of the Quaternary Period), *Doklady AN SSSR* (Reports of the Academy of Sciences of the USSR), *Izvestiia AN SSSR: Seriia geologicheskaia* (Proceedings of the Academy of Sciences of the USSR: Geology Series), *Izvestiia AN SSSR: Seriia geograficheskaia* (Proceedings of the Academy of Science of the USSR: Geography Series), *Sovetskaia geologiia* (Soviet Geology), *Geomorfologiia* (Geomorphology), *Sovetskaia arkheologiia* (Soviet Archaeology), *Izvestiia Vsesoiuznogo geograficheskogo obshchestva* (Proceedings of the All-Union Geographical Society), *Anthropozoikum* (Czechoslovakia), *Biuletyn Peryglacjalny* (Poland), and *Eiszeitalter und Gegenwart* (Federal Republic of Germany).

G. S. GANESHIN [29–349–3]

RANK (Russian, *chin*), the service position held by military personnel and civil servants, to which apply specified official rights and obligations. In prerevolutionary Russia, ranks were conferred according to the Table of Ranks, established by Peter I the Great. The concession of estate rights and privileges was connected with the attainment of a specific rank.

All civil and military ranks were abolished by the decrees of Soviet power of Nov. 10 (23) and Dec. 16 (29), 1917. Class ranks (*chiny klassnye*) have been established in the USSR for workers in the Procurator's Office. [29–602–1]

RANK, a military formation in which servicemen are ranged side by side in a line. In a two-rank formation, the servicemen of one rank take a position one step behind the men of another rank; the front rank is called the first rank and the rear rank, the second. Both formations may be either close or open. In close formation the intervals between the men within a rank are equal to the width of a hand; in open formation the interval is one step or a distance ordered by the commander. [29–1138–2]

RAW SILK, an industrial thread of natural silk, obtained in cocoon reeling by combining lengthwise several, usually five to ten, cocoon filaments; the filaments are firmly cemented together with sericin. Raw silk must be uniform with respect to thickness, smoothness (the absence of thickenings or breaks on short segments of the fiber), and cohesion of the filaments. Its mechanical properties are higher than the properties of the cocoon filaments: the breaking strength is 15 percent higher and the extensibility is 10–15 percent higher. More than one-half of all the raw silk produced is processed into thrown silk. Raw silk, which is usually produced in crosswound skeins, is used to manufacture dress fabrics, sewing threads, and other articles. [29–1110–2]

READER, a device for the viewing and reading of enlarged optical images of microfilms or microphotocopies. A reader is a projector in which the image of a microfilm frame is projected, by means of an objective and a system of mirrors, on a screen that is built into the device or on an external screen. Depending on the principle of their operation, readers are divided into devices for viewing microfilms and microphotocopies in transmitted light or in reflected light. The most widely used readers are table models, which make it possible to view both microfilms and microphotocopies—for example, microcards or microfiches—on either a transparent or an opaque substrate.

According to their design, readers are divided into devices with a diffusely reflecting screen and devices with a translucent screen. The components of a reader with a diffusely reflecting screen may include a mirror attachment for projecting images on an external screen.

In a reader with a diffusely reflecting screen, light from an electric lamp passes through a heat filter and a system of lenses and falls on a microfilm frame. The optical image of the microfilm frame is projected, by means of an objective and a mirror, on a screen located within a housing that shields the screen from light. Such a housing makes it possible to use the reader in undarkened rooms.

In a reader with a translucent screen, rays of light pass through a heat filter and fall on a microfilm frame. The image of the microfilm frame is projected on the translucent screen by means of an objective and a system of mirrors.

In working with microphotocopies, it often becomes necessary to obtain an enlarged duplicate of a document. For this purpose, a reader copier is used. In such a device, a reader and a reprographic system are integrated. The first reader-copiers, which were manufactured by Kodak (USA) in the 1930's, made copies on photographic paper. In present-day reader-copiers, enlarged copies are produced on dielectric paper or on ordinary paper by means of electrography. Work with reader-copiers is carried out in two stages. First, the required microfilm frame is retrieved on the screen; then, an enlarged copy is produced.

Readers and reader-copiers are office equipment. They are used in libraries, in the scientific and technical information departments of scientific research institutes, in design organizations, and in other organizations where the type of activity requires microfilming.

A. IA. MANTSEN [29–650–1]

RECOVERY OF SOLD PROPERTY, in Roman law and later in civil law, the retaking of property from a buyer on grounds that arose before the sale.

Under Soviet law, recovery of sold property is regulated by the civil codes of the Union republics—for instance, Articles 250 and 251 of the Civil Code of the RSFSR. The codes specify that the seller is obliged to reimburse the buyer for the loss suffered if the buyer is deprived of the goods by the judgment of the court. Both the buyer and seller must be party to the proceedings and must take part in them on the side of the buyer. Failure of the buyer to

involve the seller in the case frees the seller from responsibility, provided he shows that he could have prevented the buyer's being deprived of the goods if he had taken part in the proceedings. [29–1650–1]

RECURVIROSTRA, a genus of birds of the family Charadriidae of the suborder Limicolae. The bill is long and recurved and has a flattened tip. The plumage is white with black or red. The genus comprises four species, which are distributed in Europe, Asia, Africa, America, and Australia. In the USSR there is one species, the Eurasian, or European, avocet (*R. avosetta*). The European avocet measures 45 cm in length. Its plumage is black and white, and its bill is black. The bird is found in the south, from the Danube to Transbaikalia. It lives in colonies along the flat, swampy shores of seas and salt lakes. The clutch contains four eggs, which are incubated 22 to 24 days. The diet consists of crayfish, mollusks, and aquatic insects. [29–1195–2]

RED GOLD (in Russian, *chervonnoe zoloto*), a high-purity alloy of gold and copper that was used to make chervontsi and other coins. The fineness of red gold ranged from 916 to 986, or from 88 to 94 ⅔ in the *zolotnik* system. In Russian, the term *chervonnoe zoloto* has lost its technical meaning and has been retained only in everyday language as an equivalent of "pure gold." [29–181–4]

REGIONS OF THE WORLD, the division of the land masses of the Earth into areas consisting of one or more continents or parts of continents, together with adjacent islands. The world is generally divided into the following regions: Europe, Asia, Africa, Australia, North and South America, and Antarctica. Oceania, which is sometimes included as a special island region of the world, is on occasion joined with Australia to form a dual region. The division of the world's land masses into regions should not be confused with the division into continents or into the Old World, which comprises Eurasia and Africa and was known before the discovery of America, and the New World, which comprises North and South America. Australia, Oceania, and Antarctica are disregarded in this division. [29–79–1]

REPOUSSAGE, the production of raised images on sheet metal. The reverse side of the metal sheet is laid against a block of special resin, and a special hammer is used to strike a raising tool applied most frequently to the face side. Repoussage is one of the oldest techniques used in decorative metalworking.

RESOLUTION SENSITIVITY (Russian, *informatsionnaia chuvstvitel'nost'*), a characteristic of photosensitive emulsion layers that describes their capacity to record an individual optical signal or unit of optical information and to make it discernible from adjacent recorded signals.

In ordinary silver halide photographic materials, high photographic contrast and photographic sensitivity are factors that contribute to a high resolution sensitivity; graininess and light scattering by the emulsion are factors that reduce resolution sensitivity. Thus, the index of resolution sensitivity for such films is taken as the ratio $GS/\sigma_D\omega$, where G is the increase along the ordinate of the characteristic curve per unit of length along the abscissa in the linear segment of the characteristic curve, S is the photographic sensitivity value, σ_D is the mean square granularity (the mean square value of the variations in optical density D of a macroscopically uniform section of photographic blackening; the variations are caused by the grain structure in the section), and ω is the area of the scattering section in the image of a luminous point on the photosensitive layer. (*See* SENSITOMETRY for a discussion of the quantities G and S.)

A. L. KARTUZHANSKII [29–726–3]

RETE MIRABILE, a vascular network formed as a result of the one-time division of the original blood vessel into capillary-like branches that subsequently reunite into a single vessel.

One of the many anachronisms in terminology, the term was coined by Galen, who discovered the division of the internal right and left carotid arteries in animals into numerous small arterial branches, which then rejoined between the internal base of the skull (in the body of the sphenoid bone and the upper part of the clivus) and the dura mater of the brain. The unusual feature of this vascular network of vessels is that all the smaller vessels eventually unite into a single vessel that continues further under the same name—the internal carotid artery—and that acts as the source for the capillary network of the corresponding hemispheres of the brain. Commentators on Galen's works believed that the life spirit (*spiritus vitalis*) was transformed into the animal spirit (*spiritus animalis*) in the rete mirabile and was then distributed throughout the entire body from the brain along the nerves, as if through pipes.

In the modern literature, the term "rete mirabile" sometimes refers to the glomerular capillaries of the kidneys that join blood vessels bringing blood into the glomeruli and then taking it out (rete mirabilis artereosum) and to the sinusoids in the liver, which connect the branches of the portal vein with the roots of the hepatic veins (rete mirabilis venosum).

The rete mirabile in the wall of the swim bladder of fishes is composed of the finest precapillary arterioles, through which gas passes into the swim bladder from the blood cells. The function of the rete mirabilis is to retard the flow of blood in certain parts of the circulatory system. V. V. KUPRIIANOV [29–735–4]

RHIZOCTONIA ROT OF CITRUS, a disease of the root system of citrus crops caused by the fungus *Rhizoctonia violacea*. A reddish-violet mycelial tomentum forms on the roots and penetrates the tissue. Affected roots wither, and the cortex separates and is converted into a semifluid, blackish, foul-smelling mass. The plants usually die. The disease occurs in citrus-growing regions. Control measures include digging up and burning diseased plants and disinfecting the soil after removal of the plants. [29–250–2]

ROLLER-BIT DRILLING, a drilling method that uses a roller bit (*see* DRILL BIT). The method was first used in the USA in the 1920's and in the USSR in the 1930's to drill oil and gas wells.

In roller-bit drilling, rock is cut by steel or hard-alloy teeth projecting from rolling cutters, which rotate on the drill-bit bearings. In turn, the drill bit rotates at a rate of 60–600 rpm and presses against the bottom hole with a high axial force of 500–2,000 kg per cm of the bit diameter. The teeth of the rolling cutters roll over the bottom hole and, owing to the large stresses that develop in the area of contact between the teeth and the rock, cut the rock by crushing and chipping. As the hardness of the rock increases, the rotation rate decreases and the axial force increases. The rock that is cut at the bottom of a well is removed to the surface by washing, blowing, or a combination of washing and blowing.

Roller-bit drilling is carried out by stationary, self-propelled, or mobile drilling rigs using the rotary method (*see* ROTARY DRILLING) or the turbine method (*see* TURBODRILLING) of transmitting torque to the roller bit. Less often, electrodrills are used.

Roller-bit drilling is used to drill deep (up to several kilometers in depth) exploratory, oil, and gas wells. It is also used to drill blastholes in underground and open-pit mining, to bore raises in underground mines, and to sink mine shafts.

The efficiency of roller-bit drilling is evaluated on the basis of the shift or monthly drilling rate per rig and the volume of drilling with a roller bit before the bit is replaced. Depending on the hardness of the rock and on the field of application, the cited indicators vary over a wide range. As of 1978, roller-bit drilling was superior to other drilling methods in performance.

ROOFING TILE, pieces of ceramic roofing material made of fired clay, a cement-sand mortar, or a lime-sand mortar processed in an autoclave (silicate tile). The most common clay tile is made from plastic clays having a low fusion point (sometimes with the addition of a fireclay).

Depending on the shape and the molding method, roofing tile may be classified as grooved (both pressed and strip types) and flat (strip type); a ridge tile is also produced to cover the ridge of a roof. Depending on the composition of the clay and the firing method, tile may have a natural color ranging from brick red to a yellow-gray. For decorative purposes tile is sometimes coated with a colored glaze. Cement tile can be colored with a weatherproof pigment through its cross section or on its surface. The advantages of roofing tile are its durability, fire resistance, impermeability to water, frost resistance, and low maintenance costs (periodic painting is not required); the disadvantages include brittleness and relatively high weight. Tile roofs should have a steep slope (more than 30°) in order to drain off water.

[29–214–2]

RUMEX, a genus of perennial or annual herbs or subshrubs of the family Polygonaceae. The erect branching stem is for the most part rough. The leaves are large and petioled. The bisexual or, less commonly, unisexual flowers are in panicled inflorescences. The fruit is a three-angled achene.

There are about 150 species of *Rumex*, distributed mainly in temperate regions of the northern hemisphere. The USSR has more than 50 species. The plants grow along roads and rivers, near fences, on floodplain meadows, and in wastelands, orchards, gardens, and fields. They are only sometimes eaten by livestock. The plants severely suppress the growth of cultivated plants, including valuable cereal grasses.

The garden sorrel (*R. acetosa*) is cultivated as a vegetable. It is sown several times throughout the summer. The leaves are gathered 18 to 25 days after sowing; if the seeds are not needed, the flower stalks are cut. Varieties of garden sorrel include Belleville, Odesskii 17, and Broad-leaved. The fresh leaves are used to prepare various foods, including canned goods (puree). The leaves contain oxalic acid, iron, and tannins. Another cultivated species is the spinach-dock, or herb patience (*R. patientia*). The species *R. confertus* is cut before seed maturation for silage.

SA (Sturmabteilung; known in English as Storm Troopers), a paramilitary unit of the National Socialist Party in Germany from 1921 to 1945. The SA was an instrument of terror used against opponents of fascism.

After the fascists seized power in Germany in 1933, the SA was turned into an auxiliary police force; members of the organization were used as guards in the Nazi concentration camps and were responsible for some types of military and paramilitary training. In early 1934 there were more than 3 million members of the SA, mostly from petit bourgeois strata. On June 30, 1934, the fascist leadership, taking advantage of unrest within the SA caused by the failure to fulfill the promises made by the Nazi leaders to the petite bourgeoisie, liquidated the discontented members; those killed included E. Röhm and other leaders of the SA who tried to use the discontent of the rank and file to strengthen their own position. After the events of June 30, the SS (Schutzstaffel), which until then had been subordinate to the command of the SA, became a separate organization. The SA was outlawed after the defeat of German fascism in 1945.

[29–1505–1]

ŠABAC, a city in Yugoslavia, in Serbia. Port on the Sava River. Population, 45,000 (1976). Šabac has zinc-smelting, chemical, wood-products, and leather industries. Flour, alcohol, vodka, meat, canned fruit and vegetables, and other food products are also manufactured. [29–790–2]

SABER CARP (*Pelecus cultratus*), also chekhon, a semianadromous or freshwater fish and frequently a school fish of the family Cyprinidae. The body is elongated and flattened. Its lateral line is irregular, with a considerable bend at the pectoral fin. The mouth is apical. The saber carp is generally 30–40 cm long, sometimes reaching 60 cm. It weighs between 300–400 g and 2 kg. It inhabits freshwaters and brackish waters, and it is distributed in the basins of the Baltic, Black, Caspian, and Aral Seas, in lakes, and in reservoirs. A pelagic fish, it lives in the depths of the water. It attains sexual maturity in the third to fifth year of life. Spawning occurs in May or June. Fecundity is about 30,000 eggs. The semianadromous forms winter in rivers. The diet consists of invertebrates and small fish. The saber carp is of commercial importance.

ŠAFAŘÍK, PAVEL JOSEF. Born May 13, 1795, in Kobeliarovo Slovakia; died June 26, 1861, in Prague. Slovak and Czech Slavicist. Figure in the Czech and Slovak national liberation movements.

Šafařík graduated from the University of Jena in 1817 and taught in a Serbian *Gymnasium* from 1819 to 1833. In 1841 he became curator of the library of Charles University, and in 1848 he became the library's director. During the Revolution of 1848, Šafařík adopted a liberal bourgeois stance. He became chairman of the society Lípa Slovanská in April 1848 and headed the Czech and Slovak delegation to the Slavic Congress, held in Prague that June.

Šafařík was the first Slavicist to apply the comparative historical method to the study of the Slavic peoples. His principal works *Slavic Antiquities* (Russian translation, vols. 1–2, 1837–48) and *Slavic Ethnography* (Russian translation, 1843) provided historical substantiation for the concept of Slavic unity and demonstrated the role played by the Slavs in world history. Šafařík also wrote on mythology, paleography, Slavic languages, and Czech and Slovak literature and folklore. He and F. Palacký published the treatise *Principles of Czech Poetry* in 1818. Šafařík's *History of Slavic Language and Literature in All Its Dialects* appeared in 1826. His activity as a poet is represented by the collection of verse *A Tatra Muse With a Slavic Lyre* (1814). Šafařík's work influenced the development of Slavic studies in Russia and in other countries.

R. A. AGEEVA [29–887–1]

SÁGVÁRI, ENDRE. Born Nov. 4, 1913, in Budapest; died there July 27, 1944. Figure in the Hungarian youth movement. A lawyer by education and profession.

In 1936, Ságvári joined the Social Democratic Party of Hungary and became a leader of the All-Hungarian Youth Committee (AYC). In the following year he was sentenced to eight months in prison for his revolutionary activities. In 1940 he joined the Communist Party of Hungary and became secretary of the AYC.

Ságvári helped organize antiwar demonstrations in Budapest in 1941 and 1942, and in March 1942 he was forced to go underground. In 1944 he edited *Béke és szabadság*, the illegal newspaper of the Peace Party. Ságvári was killed during an exchange of gunfire with the police.

SAISUNAGA, a dynasty that ruled the ancient Indian kingdom of Magadha from approximately 430 B.C. to 364 B.C., or according to some sources, during the seventh and sixth centuries B.C. The dynasty consisted of two rulers: Saisunaga, who seized power through a coup, and his son Kalasoka, whose murder was arranged by Mahapadma Nanda.

Under the Saisunaga dynasty, the Magadhan state grew by subjugating other states, such as the kingdoms of Avanti and Kasi. The Saisunaga rulers supported Buddhism, and, according to tradition, the Buddhist Second Council met at Vesali during Kalasoka's reign. [29–811–6]

SAJÓ (also Slaná), a river in Czechoslovakia and Hungary, a right tributary of the Tisza River of the Danube basin. The Sajó is 229 km long and drains an area of 12,700 sq km. The river rises in the Slovak Ore Mountains and flows, for the most part, in a broad valley; in its lower course it flows along the Middle Danube Plain. The Sajó is fed primarily by rain, and freshets occur in the summer and fall. The mean flow rate is approximately 70 cu m per sec. In some years, the river freezes over for one or two months. It is used for timber flotation. The Hungarian city of Miskolc is located on the Sajó. [29–811–2]

ŠAKIAI, a city and the administrative center of Šakiai Raion, Lithuanian SSR. Šakiai is situated on the Siesartis River of the Neman River basin. The city is 61 km northwest of Kaunas and 33 km north of the Pilviškiai railroad station on the Kaunas-Kaliningrad line. Industry is represented by a metalworking shop of the Vilkaviškis Metalworks. [29–813–3]

SAKYA (also Shakya), an ancient Ksatriyan oligarchic republic and tribe in the Nepalese Terai. The city of Kapilavastu was the capital of the republic.

According to tradition, Siddhartha Gautama, the founder of Buddhism, belonged to the Sakya tribe; he is sometimes called Sakyamuni, or sage of the Sakya. Since his first followers were also Sakya and constituted the nucleus of the first Buddhist monastic community, the tribe's name is sometimes used to refer to Buddhist monks in general. [29–813–1]

ŠALČININKAI, a city and the administrative center of Šalčininkai Raion, Lithuanian SSR. Šalčininkai is located 45 km southeast of Vilnius on the Vilnius-Lida highway and has a railroad station on the Vilnius-Lida line. The city has an alcohol plant and a production combine whose products, made of fiber glass reinforced plastics, include boats and launches. [29–817–2]

SALGÓTARJÁN, a city in northern Hungary, on the Zagyva River. Capital of the *megye* (county) of Nógrád. Population, 44,000 (1976). Salgótarján is the center of the Nógrád Coalfield, from which brown coal is extracted. Industries include metallurgy, the production of mining equipment, agricultural machine building, and the manufacture of metal goods, glass, and bricks. [29–816–3]

SALLAI, IMRE. Born Dec. 17, 1897, in Erdőfülle, in the *megye* (county) of Baranya; died July 29, 1932, in Budapest. Figure in the Hungarian working-class movement.

Sallai helped found the Communist Party of Hungary (CPH) in 1918 and became a member of its Central Committee. Under the Hungarian Soviet Republic of 1919 he was deputy director of the political department of the People's Commissariat for Internal Affairs.

From 1921 to 1923 Sallai engaged in party work in Vienna. He was on the staff of the Marx-Engels Institute in Moscow from 1924 until 1928, when, at the behest of the Central Committee of the CPH, he organized an underground press in Hungary. Sallai returned to the USSR in 1929 and stayed there until 1931. In the spring of that year he became the head of the secretariat of the Central Committee of the CPH. Captured by the police in Budapest in July 1932, Sallai was executed together with S. Fürst. [29–814–3]

SALVIA (sage), a genus of perennial herbs or subshrubs of the family Labiatae. The flowers are in false whorls, which form a spicate or panicled inflorescence. The upper lip of the corolla is helmet-shaped, straight, or crescent-shaped. There are two stamens. The flowers have a unique adaptation for cross-pollination. The fruit consists of four nutlets.

The approximately 700 species occur throughout the world, primarily in the subtropics and tropics. The USSR has about 80 species, growing mainly on dry mountain slopes. The most common species is garden sage (*S. officinalis*), a usually violet-flowered subshrub that grows in the Mediterranean region. In the USSR it is cultivated for medicinal and culinary purposes in Moldavia, the southern Ukraine, and Krasnodar Krai. The leaves contain essential oil, alkaloids, and tanning substances; they are used as a flavoring in the production of liqueurs and spirits and in the fish canning industry. A tincture of leaves is used medicinally as an astringent or anti-inflammatory rinse to treat inflammations of the mouth, pharynx, and larynx. Clary (*S. sclarea*), a perennial with pinkish lilac flowers, grows in the southern Ukraine, the Crimea, the Caucasus, and Middle Asia. It is cultivated for the essential oil contained in the inflorescences; the oil is used by the pharmaceutical, distilling, confectionery, and tobacco industries. Many species, including scarlet sage (*S. splendens*), *S. coccinea*, and garden sage, are cultivated as ornamentals.

SANDING, in woodworking, the processing of workpieces with abrasive materials, such as sandpaper, and with special tools, such as brushes and wire disks, immediately after planing, shaping operations, routing, puttying, or priming. In sanding unvarnished surfaces, the abrasive materials are moved in the direction of the wood grain; otherwise, the wood fibers are cut, and subsequent application of varnish or paint causes the fibers to rise, resulting in a rough surface.

A. A. SHISHKIN [29–1298–1]

SANDING MACHINE, a woodworking machine for sanding parts and articles made of wood and wood materials. Sanding machines are divided into disk, belt, drum, bobbin, vibratory, and polishing types depending on the type of abrasive tool, the shape of the backing to which the abrasive paper is applied, and the purpose.

Depending on the workpiece feed motion, sanders may be fixed or traverse types. In the former, either the abrasive paper or the workpiece executes a reciprocating motion; in the latter, the workpiece passes through the working zone of the abrasive paper. Machines used for polishing varnished items are of the fixed type. Varnished surfaces are usually sanded on vibratory sanders, in which the abrasive paper executes an oscillating motion together with its clamping device at a rate of approximately 1,400 vibrations per min. The most productive types of sanders are wide-belt traverse types and drum sanders.

A. A. SHISHKIN and N. K. IAKUNIN [29–1296–2]

SANKARA (also Shankara). Probably born in A.D. 788; died circa 820. Indian religious philosopher and poet; reformer of Hinduism and creator of the consistently monistic system of Advaita Vedanta (nondualistic Vedanta).

Sankara was born into a Brahman family in Malabar (now state of Kerala). He became an ascetic in early childhood and studied with Govinda, a pupil of Gaudapada's. Sankara founded several religious communities. His chief works are the commentaries to Badarayana's *Brahma Sutra*, or *Vedanta Sutra*, to the Upanishads, and to the *Bhagavad-Gita*.

According to Sankara, the only and all-pervasive reality is *brahman*, the supreme objective principle that is identical to the self (*atman*, or the soul), which is the subjective principle. The

apparent plurality of the world is explained by *maya*, the special power of divinity; *maya* is the illusion that at times conceals and at other times distorts the truth. Our ignorance (*avidya*) prevents us from apprehending the unity of *brahman*, creating the world of plurality and the movement and change associated therewith.

Sankara does not acknowledge the reality of changes, which he explains as mere appearance. He refuses to grant the status of reality to the empirical world, even though he regards the latter as objective inasmuch as behind every appearance lies its hidden substratum, or pure being (*brahman*). Sankara is consistent in distinguishing between the empirical and the transcendental point of view—from which two different pictures are obtained—and he sets forth the rules governing the transition from one to the other; these rules lead to the elimination of all attributes, such as creation, movement, change, and quality, that are functions of our ignorance.

Sankara's system is crowned by his doctrine of immanent and transcendental divinity, which possesses no qualities, and of salvation (*moksha*), which is achieved by the free realization of the infinite and absolute self, acknowledgment of the self's extraempirical nature, and recognition of the essential identity of the self and *brahman*.

Sankara's works laid the foundation for the many commentaries within Vedanta, of which the best known is the *Panchapadika* by Padmapada, one of Sankara's pupils. Sankara's doctrine was exceptionally influential in the development of the traditional world view of Hinduism, its influence being felt even today; his work is deemed to have contributed to the victory of Vedic beliefs over Buddhism, which was forced out of India shortly after Sankara's time.

V. N. TOPOROV [29–833–1]

ŠANTIĆ, ALEKSA. Born May 27, 1868, in Mostar, Hercegovina; died there Feb. 2, 1924. Serbian poet associated with the liberation movement in Hercegovina.

Šantić studied at business schools in Ljubljana and Trieste. His first collection, *Poems*, appeared in 1891. He later published six more books under that title, as well as a collection entitled *On the Old Hearths* (1913). In Šantić's poetry lofty civic sentiments, intense lyricism, and a tendency toward generalized images are combined with profound social content in depictions of the hard lot of the peasants and vivid portraits of working people. His poems above love and nature display a heartfelt lyricism. The poet's faith in the victory of the working class is expressed in "Underground Song" (1920). Šantić also wrote two dramas in verse, *In the Fog* (1911) and *Hasan-Aganica* (1911).

SARCOPTIDAE (itch mites), a family of minute parasitic mites of the order Sarcoptiformes. The insects parasitize the skin of mammals, including humans, causing a burning itch (acariasis or sarcoptiasis). The light yellow body measures 0.2–0.5 mm in length. There are no eyes or tracheae. The eight pairs of short legs end in suckers or bristles. The family embraces approximately 20 species. The females burrow long, twisting passages in the skin and fill them with ova and feces. In four to seven days the larvae hatch. In another 14 days the mites attain sexual maturity and begin to burrow, forming new channels. They mate on the skin surface, after which the males die. [29–343–1]

ŠAR PLANINA, a mountain range in southern Yugoslavia, near the Albanian border. The Šar Planina is more than 60 km long and reaches an elevation of 2,760 m at Titov-Vrh. The range is composed of schists, limestones, and dolomites and exhibits karst phenomena. Mixed forests are found on the slopes, and mountain meadows are encountered at elevations above 2,000 m. [29–870–4]

SASTRI, K. A. NILAKANTA. Born Aug. 12, 1892. Indian historian. A Tamil by nationality.

Sastri is a moderately nationalistic member of the objectivist school. Most of his more than 15 books on Indian history deal with the southern part of the subcontinent. Sastri's works are rich in factual material.

[29–875–2]

SAXICOLA, a genus of birds of the family Turdidae of the order Passeriformes. The body length ranges from 12.5 to 20 cm. The genus comprises about ten species, which are distributed in Europe, Africa, and Asia.

There are four species in the USSR: the stonechat (*S. torquata*), the whinchat (*S. rubetra*), the pied stonechat (*S. caprata*), and Hodgson's stonechat (*S. insignis*). The stonechat is widely distributed throughout the USSR, inhabiting shrub-filled meadows and forest marshes. The whinchat occurs as far east as Krasnoiarsk and is commonly found in cleared forests and along forest margins. The pied stonechat inhabits the river valleys of southern Middle Asia, while Hodgson's stonechat lives on mountain meadows of the Sailiugem Range in the Altai Mountains.

Members of the genus *Saxicola* are migratory. They nest on the ground, beneath shrubs; they sometimes nest in building cracks. The clutch contains four to seven eggs, which are incubated by either the female alone or by both the female and the male. The diet consists of insects. [29–131–4]

SCABIES, a contagious skin disease of humans caused by the itch mite. Scabies occurs after direct contact with various objects and clothing of a person suffering from scabies.

Seven to ten days after infection, a rash appears in the form of tiny nodules, blisters, and slightly raised straight or curved lines about 1 cm in length (mite burrows). The rash occurs in the folds between the fingers, on the sides of the fingers, at the bends of the upper limbs, and on the front and sides of the trunk; in children, it occurs all over the body. The rash is produced by fertilized female mites, which bore into the epidermis, where they deposit their eggs. Mite reproduction is very rapid: about 150 million individuals appear within three months. Persons afflicted with scabies are disturbed by severe itching, especially at night, and in warm conditions. Ulcerations often form on the skin as a result of infections brought on by excessive scratching.

Treatment involves the application to the affected areas of Wilkinson ointment, a 33 percent sulfur ointment, a 20–25 percent soap and water emulsion of benzyl benzoate, a 60 percent sodium thiosulfate solution, or a 6 percent solution of hydrochloric acid. Scabies can be prevented by the observance of the rules of personal hygiene, periodic examination of children's groups, and the isolation and treatment of individuals afflicted with scabies and the disinfection of their belongings.

SCALE. (1) A microscopic chitinous plate on the bodies of some arthropods, mainly insects, which sometimes completely covers the body. As a result of their optical properties, the scales as a rule determine the coloration of the animal. Butterflies have scales which are particularly developed. Bristletails, springtails, weevils, mosquitoes, and some Hymenoptera have scales, as well as some mites.

(2) Various growths on plants, usually flat and having a protective function. Frequently "scale" refers to the base of a leaf that remains on the stalk after the leaf has fallen off and that forms a peculiar shell on the stem. [29–529–1]

SCALE (also plate), a hard metameric protective plate of the epidermis in vertebrates, including fish, reptiles, birds, and some mammals.

The scales of fossil Agnatha and fossil fishes were mesodermal in origin and were formed by bony tissue (dentin, bone). Scales are distributed on the body in regular diagonal rows in the direction of the collagen fibers of the skin. In addition to their protective function, they fulfill musculoskeletal functions. In the phylogenesis of the lowest, originally aquatic, vertebrates, such as cyclostomes, fishes, and amphibians, the origin of the scales is the placoid scales of fossil Thelodontidae and cartilaginous fishes, as represented by dentin spines and teeth that were periodically replaced as the animal grew (*see* PLACOID SCALE). The cosmoid scales, ganoid scales, cycloid scales, and ctenoid scales of the bony fishes are complex phylogenetic derivatives of the original type of scale (*see* COSMOID SCALE; GANOID SCALE; CYCLOID SCALE; and CTENOID SCALE). These scales are characterized by cyclical growth and the formation of annual rings, which make it possible to determine the age of the fish.

Among amphibians, bony plates similar to fish scales are found in some stegocephalians and modern Apoda, such as the Caeciliidae, including water snakes. The horny plates of reptiles, birds, and some mammals are formed by the keratinization of the outermost epidermal layer. They prevent the skin from drying out and protect it from physical damage. The horny plates are usually replaced through periodic molting or desquamation. In certain reptiles, such as crocodiles and tortoises, the horny plates sometimes fuse with the secondary dermal ossifications and cover the entire body. In birds they cover only the legs, and in mammals, for example, marsupials, rodents, insectivores, and some others, they are usually found on the tail. The secondary development of large plates on the body is observed in armadillos, in which they overlie bony plates, and in pangolins.

V. N. IAKOVLEV [29–531–3]

SCALE, part of the reading device of a measuring instrument, consisting of a system of markings (dots or lines arranged in some definite sequence) with numbers or other symbols at some of the markings representing a series of consecutive values of the measured quantity.

Scale parameters, such as scale limits and the value of a division of the scale (that is, the difference between scale values corresponding to two adjacent markings), depend on the inherent measurement limits of the measuring mechanism, on the sensitivity of the instrument, and on the required reading precision. The arrangement of the divisions, which can be in a circle, an arc, or a straight line, depends on the design of the reading device, while the scale itself may be uniform, quadratic, logarithmic, and so on. The main divisions of the scale, corresponding to the numerical values, are marked off by longer or thicker lines. Readings are made by the naked eye on scales the distance between whose divisions is 0.7 mm or higher; smaller intervals require the use of a magnifying glass or microscope. Fractional estimates of scale divisions are made with the aid of verniers. [29–1252–5]

SCALE INSECT, the common name for any one of numerous homopterous insects of the suborder Coccoidea, which unites representatives of the families Ortheziidae, Margarodidae, Asterolecaniidae, Pseudococcidae, and Eriococcidae.

Scale insects are tiny sucking insects with marked sexual dimorphism. The males have wings, usually the first pair; the extremities are normally developed, and there are two setae or a tuft of setae at the caudal end of the abdomen. There is no mouth apparatus (the males do not feed in the adult stage). The females are wingless and larva-like and are covered with a waxy coating secreted by numerous glands. The head is fused with the prothorax. The mouth apparatus is a sucking one. In a number of species the legs are reduced or absent. Segmentation of the abdomen is not always marked. Most species lay eggs; some species are viviparous. Fertility is very high; many forms produce two, sometimes as many as four, generations in a year. First-stage larvae (wanderers) actively move over the host plant and may be carried by wind. Upon attaching themselves to a plant, the larvae lose their mobility; after molting, the next-stage larvae again seek a feeding ground. Females have three stages (instars) of larval growth. Males have two additional nonmotile, nonfeeding, nymphal stages. Adult females of some species can actively crawl over the host plant. Prior to egg laying, many forms abandon their feeding ground and disappear from view.

There are more than 1,600 species of scale insects distributed throughout the world; there are about 250 species in the USSR. Scale insects are most numerous in warm climates. Many are pests of fruit, industrial and ornamental crops, and greenhouse plants. Best known are the greenhouse scale (*Orthezia insignis*), the cottony-cushion scale (*Icerya purchasi*; a pest of citrus plants, infestation with which necessitates quarantine), the bamboo scale (*Antonina crawi*), the citrus mealybug (*Planoccocus citri*), the grape mealybug (*Pseudococcus maritimus*), the grape scale (*Aspidiotus uvae* or *Eulecanium persicae*), the Comstock mealybug (a pest of mulberry), and the olive scale (*Parlatoria oleae*). Some species secrete beneficial substances that are used in the paint and varnish industry; they include the lac insect and the cochineal insect, which yields the red dye carmine.

SCHACHT, JOSEPH. Born Mar. 15, 1902, in Ratibor (Racibórz); died Aug. 1, 1969, in New Jersey. Islamic scholar; specialist in Islamic law. Editor and one of the founders of the journal *Studia Islamica*; editor of the second edition of the *Encyclopedia of Islam*. Of German extraction.

Schacht left fascist Germany in 1934 and moved to Egypt, where he taught at the University of Cairo until 1939. From 1946 to 1953 he was a professor of Islamic studies at Oxford, and from 1953 to 1959 he headed the Arabic studies department at the State University of Leiden. In 1959 he became a professor of Arabic and Islamic studies at Columbia University in New York City.

Schacht believed that the formation of the basic system of Islamic law had been completed by the eighth century. Although he dealt with Islamic law chiefly in a historical and sociological context, Schacht saw the law as self-contained.

SCHÄDEL, GOTTFRIED JOHANN. Born 1680's in Wandsbek, near Hamburg; died Feb. 10 (21), 1752, in Kiev. German architect active in Russia from 1713; representative of the baroque style.

From 1716 to 1726, Schädel directed the construction of A. D. Menshikov's palaces in St. Petersburg and Oranienbaum (present-day Lomonosov). In 1730 he worked on the designs for the bell tower of the Don Monastery in Moscow. He worked in Kiev from 1730, where he built the bell tower in the Kiev-Pecherskaia Laura and a number of other buildings. [29–1078–4]

SCHADOW, a family of German artists of the late 18th and 19th centuries.

Johann Gottfried Schadow. Born May 20, 1764, in Berlin; died there Jan. 27, 1850. Sculptor in the classical style.

J. Schadow studied in Berlin and, from 1785 to 1787, in Rome. In 1788 he became the director of the royal school of sculpture in Berlin. In 1805 he became the vice-director, and in 1815 the director, of the Berlin Academy of Arts. Schadow often used classical motifs. He created imposing official monuments, such as the quadriga with the figure of Victory on the Brandenburg Gate in Berlin (copper, 1788–94); he also produced works noted for their sculptural and emotional freedom and, in some cases, for their sensitive portrayal of their subjects, such as the sculpture *The Princesses Luise and Frederike*. Schadow was also a graphic artist and art theorist.

Friedrich Wilhelm von Schadow. Born Sept. 6, 1788, in Berlin; died Mar. 19, 1862, in Düsseldorf. Romantic painter; one of the founders of the Düsseldorf school. Son of J. Schadow.

F. von Schadow visited Rome several times. In 1816 and 1817 he painted frescoes in the Casa Bartholdi that dealt with the legend of Joseph; since 1877 they have been in the National Gallery in Berlin. In 1819, Schadow became a professor at the Berlin Academy of Arts; from 1826 to 1859 he was director of the Düsseldorf Academy. Schadow was an outstanding teacher; his students included K. F. Lessing, A. Rethel, A. Feuerbach, and K. W. Hübner.

SCHAFFHAUSEN, a city in Switzerland, on the right bank of the Rhine. Capital of Schaffhausen Canton. Population, 35,000 (1975). The city manufactures watches, machine tools, instruments, textiles, and chemical products. [29–890–2]

SCHÄFFLE, ALBERT EBERHARD FRIEDRICH. Born Feb. 24, 1831, in Nürtingen; died Dec. 25, 1903, in Stuttgart. German and Austrian economist, sociologist, and state figure.

Schäffle was a professor of political economy at the University of Tübingen from 1860 to 1868 and the University of Vienna from 1868 to 1871. He served as the Austrian minister of commerce and agriculture in 1871 and edited the journal *Zeitschrift für die gesamte Staatswissenschaft*.

Schäffle belonged to the organismic school of sociology and shared the views not only of A. Comte and H. Spencer but of such German classical idealists as G. Hegel. He believed that the organic unity of society resulted from the transformation of interacting subjective wills and judgments into a "collective consciousness," or "spirit of the people." According to Schäffle, a feature of the "social body" is the ideal, spiritual-psychological relation between individuals that is embodied in their symbolic and direct actions. This relation differs fundamentally from that between cells in an organism.

In the later editions of his principal work, *The Construction and Life of Social Bodies* (vols. 1–4, 1875–78), Schäffle grew increasingly cautious in his use of bioorganismic analogies and treated them as a methodological tool. At the same time, the idealist tendencies in his works became more prominent.

In economic theory, Schäffle stressed the ethical and volitional nature of economic life and sought to furnish a rational ethical and anthropological foundation for it. A prominent representative of Katheder-socialism, he described as socialist any state intervention in the economy and urged cooperation between the proletariat and the bourgeoisie. In the words of F. Engels, Schäffle's socialism was "merely a feudal reaction" to the development of capitalism (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 35, p. 140).

SCHALLY, ANDREW VICTOR. Born Nov. 30, 1926 in Vilno, Poland. American physician.

Schally graduated from McGill University in Canada in 1955. He served as an assistant in biochemistry at the National Institute of Medical Research in London from 1949 to 1952 and worked in the psychiatry department of McGill University in Montreal from 1952 to 1957. He has lived in the United States since 1957. Schally was an assistant professor of physiology and biochemistry at the college of medicine at Baylor University in Houston from 1957 to 1962. In 1962 he became chief of the polypeptide and endocrinology laboratory of a hospital in New Orleans. He was an adjunct professor of medicine at a university in New Orleans from 1962 to 1967, becoming a professor in 1967.

Schally's work has been devoted mainly to the isolation from the hypothalamus of releasing hormones, in particular, the luteinizing hormone-releasing factor and the thyrotropin-releasing factor. He studies the substances' structure, synthesis, and clinical use.

Schally won a Nobel Prize in 1977 jointly with R. Guillemin and R. S. Yalow. IU. A. PANKOV [29–814–4]

SCHAPPER, KARL. Born Dec. 30, 1812, in Weinbach; died Apr. 29, 1870, in London. Figure in the German and international working-class movement.

From his early youth Schapper led the life of a professional revolutionary. He helped found the League of the Just in 1836, the German Workers' Educational Society in 1840, and the Fraternal Democrats in 1845, and he took part in the activities of all three organizations. He was among those who invited K. Marx and F. Engels to reorganize the League of the Just.

In 1847, Schapper became a member of the Communist League. He was chairman of the league's First and Second Congresses and a member of the league's Central Committee. During the Revolution of 1848–49, he became a leader of the Cologne Workers' Union.

After the defeat of the revolution, Schapper fell under the influence of voluntaristic and conspiratorial ideas; together with A. Willich, he led an adventuristic sectarian faction within the Communist League. In 1856, however, he realized that he had been in error and resumed friendly relations with Marx and Engels. In 1865, Schapper became a member of the General Council of the First International.

SCHÄRF, ADOLF. Born Apr. 20, 1890, in Nikolsburg, now Mikulov, Czechoslovakia; died Feb. 28, 1965, in Vienna. Austrian state figure; a jurist by education.

Schärf joined the Social Democratic Party of Austria in 1912. He served in the army during World War I, and when the war ended, he entered government service. His participation in the social democratic movement resulted in his arrest in 1934, 1938, and 1944. After the liberation of Austria in April 1945, Schärf served as secretary of state in the Provisional Government of Austria from April to December 1945. In the same year he helped organize the Socialist Party of Austria (SPA). From December 1945 to May 1957 he was both vice-chancellor of Austria and chairman of the SPA. Schärf became president of the Austrian republic in 1957. [29–1152–1]

SCHARF, ERWIN. Born Aug. 29, 1914. Figure in the Austrian working-class movement.

Scharf joined the Social Democratic Party of Austria in 1934. He lived abroad during the period from 1938 to 1945, when Austria was part of fascist Germany, and took part in the antifascist struggle as a member of the Austrian freedom battalion of the Yugoslav National Liberation Army.

Scharf became a member of the Socialist Party of Austria in 1945 but was expelled for criticizing the opportunism of the party's leaders. He subsequently organized the League of Progressive Socialists, which was later renamed the Socialist Workers' Party of Austria. Scharf was elected chairman of the party. After the party merged with the Communist Party of Austria in July 1956, he was named a member of the Politburo of the Central Committee of the CPA.

Between 1957 and 1965, Scharf was editor in chief of the newspaper *Volkstimme*, the main press organ of the CPA. He was named secretary of the Central Committee of the CPA in 1965 and editor in chief of the journal *Weg und Ziel*, the party's theoretical organ, in 1974.

Scharf was awarded the Order of Friendship of Peoples in 1974. [29–872–5]

SCHARNHORST, GERHARD JOHANN DAVID VON. Born Nov. 12, 1755, in Bordenau, Hanover; died June 28, 1813, in Prague. Prussian military figure. General (1807).

The son of a sergeant major, Scharnhorst entered the Hanoverian Army in 1777 and served in the artillery. After joining the Prussian Army in 1801, he became head of the German War College in Berlin in 1802 and was knighted in 1804. In 1806, during the war with France, Scharnhorst served as chief of staff to the commander in chief, the duke of Braunschweig, and fought in battles at Auerstedt and Preussisch Eylau. In July 1807 he was appointed director of the war department, head of the general staff, and chairman of the commission for the reorganization of the army. In 1808, Scharnhorst headed the newly re-created war ministry, although he did not hold the rank of minister.

Scharnhorst and A. Gneisenau significantly improved the army's organization and its officer training. They made progressive changes in tactics, shortened the length of mandatory service (as a result of which a trained reserve was created), and prepared the way for military conscription, which was introduced in 1813. Because Scharnhorst supported war against France, he was forced to retire in 1811 at the insistence of the French government.

Serving in the war of liberation of 1813 as chief of staff to General G. Blücher in the Silesian Army, Scharnhorst was critically wounded in fighting near Lützen in May 1813.

SCHAROUN, HANS BERNHARD. Born Sept. 20, 1893, in Bremen; died Nov. 25, 1972, in West Berlin. German architect (West Berlin).

From 1926 to 1932, Scharoun studied in the Academy of Arts in Breslau (present-day Wrocław, Poland). He developed the traditions of expressionism, creating asymmetrical, often curvilinear, compositions and juxtaposing elements of geometrical rationalism with organic form. His works include the philharmonic hall in West Berlin (1956–63) and the "Romeo and Juliet" apartments in Stuttgart (1955–59).

SCHAUDINN, FRITZ RICHARD. Born Sept. 19, 1871, in Röseningken; died June 22, 1906, in Hamburg. German protistologist.

In 1894, Schaudinn began working at the Zoological Institute of the University of Berlin, first as an assistant and then as a docent. In 1904 he became head of the protistology department created by him at the Imperial Ministry of Health in Berlin. In 1906 he moved to Hamburg, where he organized a department of protozoology at the Institute of Marine and Tropical Diseases.

Schaudinn's main works dealt with the study of free-living protozoans that are mainly parasitic to animals and man. He described the life cycle of coccidians, the stages of development of trypanosomes and spirochetes, and the cycle of the malaria plasmodium. In 1905, together with E. Hoffmann, he discovered the syphilis pathogen—*Spirochaeta pallida* (or *Treponema pallidum*).

Schaudinn founded (1902) the journal *Archiv für Protistenkunde*. He was a foreign corresponding member of the St. Petersburg Academy of Sciences (1905).

SCHEEL, HEINRICH. Born Dec. 11, 1915, in Berlin. German historian and social figure (German Democratic Republic). Academician of the German Academy of Sciences (1969).

During the fascist dictatorship in Germany, Scheel took part in the German resistance movement. He joined the antifascist organization led by H. Schulze-Boysen and A. Harnack and in 1943 was sentenced to a long prison term. After being freed in 1945, Scheel taught at the Humboldt University of Berlin; he became a professor at the university in 1960. A staff member of the Institute of History of the German Academy of Sciences, he was named the academy's vice-president in 1972.

Scheel's principal works deal with the history of Germany in the late 18th and early 19th centuries, particularly the history of revolutionary-democratic movements in the period. Scheel has also written on the German antifascist movement and its historiography.

WORKS

Süddeutsche Jakobiner: Klassenkämpfe und republikanische Bestrebungen im deutschen Süden Ende des 18. Jahrhunderts, 2nd ed. Berlin, 1971. [29–1080–2]

SCHEEL, WALTER. Born July 8, 1919, in Solingen. State figure of the Federal Republic of Germany (FRG).

Scheel studied economics and became a businessman. He joined the Free Democratic Party (FDP) in 1948 and was elected a member of the Bundestag in 1953. He served as vice-president of the Bundestag from 1967 to 1969.

From 1961 to 1966, Scheel was minister for economic cooperation in the coalition government formed by the Christian Democratic Union, the Christian Social Union, and the FDP. He was chairman of his party from 1968 to 1974 and subsequently honorary chairman. From 1969 to 1974, Scheel served as both vice-chancellor and minister of foreign affairs in the coalition government formed by the FDP and the Social Democratic Party of Germany. He was directly involved in negotiating treaties between his country and the USSR (signed 1970), the Polish People's Republic (1970), the German Democratic Republic (1972), and the Czechoslovak Socialist Republic (1973). Scheel was president of the FRG from 1974 to 1979. [29–1080–1]

SCHEELE, KARL WILHELM. Born Dec. 9, 1742, in Stralsund; died May 21, 1786, in Köping. Swedish chemist. Member of the Royal Swedish Academy of Sciences (1775).

Trained as a pharmacist, Scheele worked in apothecary shops in various Swedish cities, where he also carried out chemical research beginning in 1757. He discovered many inorganic and organic substances. He showed (1774) that pyrolusite, a naturally occurring manganese dioxide considered to be a variety of magnetic iron ore, is a compound of an unknown metal. He obtained chlorine by the action of hydrochloric acid on pyrolusite during heating (1774) and glycerin by the action of lead oxide on plant oils and animal fats. From natural molybdenite and tungsten minerals (scheelite) he obtained the corresponding molybdic (1778) and tungstic (1781) anhydrides. He discovered silicon tetrafluoride (1771), barium oxide (1774), hydrogen arsenide (1775), and a number of acids, including tartaric acid (1769), fluosilicic and hydrofluoric acids (1771), arsenic acid (1775), and oxalic (1776), lactic (1780), and prussic (1782) acids. He discovered (1777; at the same time as F. Fontana) the ability of freshly roasted charcoal to absorb gases.

In the work *Chemical Treatise on Air and Fire*, Scheele described the preparation and properties of "fire air" and showed that atmospheric air is composed of two "types of air": "fire air" (oxygen) and "phlogisticated air" (nitrogen). However, J. Priestley is credited with the discovery of oxygen (1774), since Scheele's work was not published until 1777.

SCHEELITE (named after K. W. Scheele), a mineral of the tungstate class, with a chemical composition $CaWO_4$. Admixtures include Mo (up to 25 atomic percent in molybdoscheelite and more than 25 atomic percent in seyrigite), Cu (up to 25 atomic percent in cuproscheelite), Sr, Mn, Nb, Ta, and F.

Scheelite crystallizes in the tetragonal system, forming dipyramidal crystals; penetration twins are known to exist. Grains and granular masses are common, and pseudomorphs of scheelite after wolframite often occur. Scheelite may be colorless, white, gray, yellowish, or, more rarely, brown, green, or black in color, with a greasy to adamantine luster. It is brittle and has perfect cleavage. The hardness varies from 3 to 5 on Mohs' scale, and the density is 5,500–6,170 kg/m^3. The mineral's luminescence in ultraviolet light (ranging from bright blue to yellow) is related to the Mo content.

The largest agglomerations of scheelite are confined to skarns, where the mineral occurs in association with garnet, pyroxene, plagioclase, amphibole, quartz, molybdenite, and other minerals. It is commonly found in high-temperature greisens, quartz-ore veins, and stockworks together with wolframite, cassiterite, fluorite, gold, and other minerals. In low-temperature hydrothermal deposits, it is associated with ferberite, antimonite, or cinnabar. Accessory scheelite has been found in granites and metamorphic rocks. Scheelite also sometimes occurs in pegmatites and alpine veins, as well as in the oxidation zone; it is converted to alluvial deposits upon weathering. Scheelite is the most important ore of tungsten; it also serves as an ore of molybdenum. The largest deposits are located in the USSR, the United States, and Korea.

SCHEER, REINHARD KARL FRIEDRICH VON. Born Sept. 30, 1863, in Obernkirchen; died Nov. 26, 1928, in Marktredwitz. German admiral.

Scheer joined the navy in 1879. From 1909 to 1911 he was chief of staff of the High Sea Fleet, from 1911 to 1913 head of the public affairs section of the Navy Department and an associate of A. von Tirpitz, and from 1913 to 1915 commander of a squadron of battleships. In January 1916, Scheer was made commander of the High Sea Fleet, which he led in the battle of Jutland of 1916. Scheer waged unlimited submarine warfare, but was unable to bring about a complete blockade of Great Britain or to weaken the blockade of Germany. From August to November 1918, Scheer was chief of the German Admiralty Staff. Scheer was the author of the memoir *Germany's High Sea Fleet in the World War* (Russian translation, 1940). [29–1080–3]

SCHEFFERVILLE, a city in Canada, on the Labrador Peninsula, in the province of Quebec. Population, 3,300 (1971). Schefferville was founded in 1954 in connection with the development of the Knob Lake iron ore deposit. The ore is shipped out by the railroad that connects Schefferville with the port of Sept-Îles. [29–1167–4]

SCHEIDEMANN, PHILIPP. Born July 26, 1865, in Kassel; died Nov. 29, 1939, in Copenhagen. Figure in the right wing of the German social democratic movement.

Scheidemann, a typographer by trade, joined the Social Democratic Party of Germany in 1883 and became a member of its administrative board in 1911. He was a member of the Reichstag from 1903 to 1918 and again from 1920 to 1933. During World War I he was a social chauvinist.

Seeking to avert a revolution, Scheidemann joined the monarchist government of Max of Baden in October 1918. The November Revolution of 1918 brought about the collapse of the monarchy, and on November 9 Scheidemann proclaimed the establishment of a republic. He became a member of the new government, the Council of People's Commissars, which sought to prevent the further development of the revolution. Between February and June 1919, he headed the first government of the Weimar Republic. He served as mayor of Kassel from 1920 to 1925. Scheidemann emigrated after the fascist dictatorship was established in Germany. [29–1083–1]

SCHEINER, CHRISTOPH. Born July 25, 1575, in Wald, near the city of Mindelheim; died July 18, 1650, in Neisse. German astronomer, physicist, and mathematician.

Scheiner's principal works were in the field of observational astronomy. In 1611, independently of Galileo and I. Fabricius, he discovered spots and faculae on the sun and determined the period of the sun's rotation and the tilt of its axis relative to the plane of the ecliptic. In 1613, Scheiner constructed a telescope that is considered the world's first refractor. [29–1084–1]

SCHEINER, JULIUS. Born Nov. 25, 1858, in Cologne; died Dec. 20, 1913, in Potsdam. German astronomer.

In 1888, Scheiner and H. Vogel determined the radial velocities of stars by photographing stellar spectra. This enabled them to determine the orbit of the eclipsing variable star Algol and to explain the cause of the variations in its brightness.

SCHELDT (Dutch and Flemish, Schelde; French, Escaut), a river in France and Belgium and in the Netherlands, where it forms an estuary. The Scheldt is 430 km long and drains an area of 35,500 sq km. It flows across the plains of Flanders and empties into the North Sea through the estuary known as the West Scheldt. Until 1867 it also formed an estuary called the East Scheldt. The river's principal tributaries are the Lys and the Rupel.

In its lower course, the Scheldt is subject to tides as far as the city of Ghent; the tides reach an amplitude of 3.8 m at the river's mouth. In the Scheldt's delta, the river and its branches have been diked to protect the adjoining land from floods. High water occurs during the cold months. The mean flow rate is approximately 100 cu m per sec.

The Scheldt is navigable as far as the city of Cambrai in France. Oceangoing vessels can sail as far as Antwerp. A system of canals connects the river to the Senne, Somme, and Meuse (Maas). The Belgian cities of Ghent and Antwerp are situated on the Scheldt. [29–1118–4]

SCHELER, MAX. Born Aug. 22, 1874, in Munich; died May 19, 1928, in Frankfurt am Main. German idealist philosopher; one of the founders of axiology, the sociology of knowledge, and philosophical anthropology.

Scheler was a professor in Cologne from 1919 to 1928. He was influenced significantly by the philosophy of life and E. Husserl's phenomenology; in the mid-1910's he turned to Catholic religious philosophy (*On the Eternal in Man*, 1921), but later he evolved a pantheistic and personalist metaphysics.

Scheler's philosophy was influenced by a keen sense of the crisis in European culture, the source of which he saw in the triumph of the bourgeois spirit with its cult of profit and gain. Rejecting socialism, which he regarded as a "condensed form" of the same utilitarianism of the bourgeois spirit, he set his hopes in his system of ethics on a "third path"—the awakening of a feeling of value in the individual consciousness. Seeking to overcome the abstractness and formalism of Kantian ethics through the use of the phenomenological method, Scheler attempted to construct a hierarchy of objective values (*Formalism in Ethics and Material Value Ethics*, vols. 1–2, 1913–16) and introduced a distinction between abstract values and empirical variables: according to Scheler, it is not values as such but the historical forms of their existence that are relative. Influenced by St. Augustine and Pascal, Scheler contrasted the logic of intellect with the logic of feeling, which he interpreted as an intentional act whereby the knowledge of value is realized. Love, according to Scheler, is an act of ascent, accompanied by instantaneous insight into the highest value of an object; the specific character of love is that it can be directed only toward an individual as the bearer of value, but not toward value as such (*The Nature of Sympathy*, 1923). In his works on the sociology of knowledge, which include *Forms of Knowledge and Society* (1926), he viewed the diversity of social norms and values as a consequence of the diversity of historical conditions that hinder or help the realization of various "life," "spiritual," and religious values.

Scheler's characteristic dualism—the world of values as ideal tasks and the real existence of the present—achieved particular acuity in his unfinished work on philosophical anthropology, *The Place of Man in the Universe* (1928). In this work the powerful but blind "gust" of life and the all-comprehending but powerless spirit are put forth as the fundamental principles of human existence. Scheler greatly influenced the subsequent development of idealist philosophy, becoming a link between the philosophy of life and existentialism.

D. N. LIALIKOV [29–1101–1]

SCHELLING, FRIEDRICH WILHELM JOSEPH VON. Born Jan. 27, 1775, in Leonberg; died Aug. 20, 1854, in Bad Ragaz, Switzerland. German philosopher, representative of German classical idealism.

Schelling studied at the theological seminary at Tübingen from 1790 to 1792; two of his fellow students were Hölderlin and Hegel. He was a professor in Jena from 1798 to 1803, where he became friendly with a romantic circle that included August von Schlegel and Friedrich von Schlegel. He moved to Munich in 1806; he was a professor at the universities of Erlangen from 1820 to 1826, Munich from 1827, and Berlin from 1841.

Several distinct periods may be distinguished in Schelling's philosophy: the philosophy of nature (from the mid-1790's), transcendental or aesthetic idealism (1800–01), the philosophy of identity (to 1804), the philosophy of freedom (to 1813), and positive philosophy, or the philosophy of revelation (until the end of his life).

Schelling was strongly influenced by J. H. Fichte, to the interpretation of whose ideas he devoted his first philosophical works. Proceeding from Fichte's teaching about nature, which was regarded as a means to the realization of a moral end, Schelling set himself the task of revealing consecutively all the stages of development of nature on the way to this lofty goal, that is, examining nature as an expedient whole, as a form of the unconscious life of reason, the purpose of which is to engender consciousness. The problem of correlating consciousness and the unconscious is predominant at all the stages of Schelling's development. Unlike Fichte, nature for Schelling ceases to be merely a pure means, a material on which practical reason tests its forces, and becomes instead an independent reality—intelligence in the making. The dialectic method used by Fichte in analyzing the activity of the self is expanded by Schelling to include an analysis of natural processes; every natural body is interpreted as a product of the work of a dynamic principle, the interaction of opposing forces, including positive and negative electrical charges and positive and negative magnetic poles. In this regard, Schelling was influenced by the discoveries of Galvani, Volta, and Lavoisier in physics and chemistry and the work of Haller and Brown in biology. Schelling's philosophy of nature was antimechanistic. The principle of expediency, the basis of the living organism, became for him a general principle for explaining nature as a whole; inorganic nature appeared to him as an underdeveloped organism. His philosophy of nature had an important influence on many naturalists, including H. Steffens, C. G. Carus, and L. Oken, and on such romantic poets as L. Tieck and Novalis. Even in this period Schelling was closer to the traditions of Neoplatonism (*On the World Soul*, 1798) than to the ethical idealism of Fichte.

Schelling regarded the philosophy of nature as an organic part of transcendental idealism, which showed how the development of nature was complete with the appearance of the conscious ego.

This organic part has to be supplemented with another part that explores the development of the ego itself. Schelling's *System of Transcendental Idealism* (1800; Russian translation, 1936) was devoted to this theme. The activities of the ego can be broken down, according to Schelling, into theoretical and practical spheres. The former begins with sensation, proceeds to reflection, conception, and judgment, and finally reaches the highest level—reason—the point at which the theoretical ego recognizes itself as independent and enterprising, that is, it becomes the practical ego, or will. Will, in turn, passes through a series of developmental stages, the highest of which is moral activity, which has itself as its goal. If in the theoretical sphere consciousness is determined by the unconscious activity of the ego, then in the practical sphere, on the contrary, the unconscious depends on consciousness and is determined by it. For Fichte, these two diverse processes coincide only at infinity, to which the realization of the cognitive and the moral ideal is also ascribed. Relying on Kant's *Critique of Judgment* and the aesthetic teaching of F. Schiller, Schelling regarded art as that sphere wherein the opposition of the theoretical and the moral-practical is overcome; the aesthetic principle appears as a balance: the total harmony of conscious and unconscious activity, the coincidence of nature and freedom, the identity of sensible and moral principles. In artistic activity and in works of art, infinity is reached—an ideal unattainable in either theoretical cognition or moral activity. The artist, in Schelling's opinion, is a genius, that is, an intelligence that functions like nature; a contradiction insurmountable by any other means is resolved in the artist. Accordingly, philosophy of art for Schelling is an "organon" (implement) of philosophy and its conclusion. Schelling developed these ideas further in *Philosophy of Art* (published 1907; Russian translation, 1966), a work that expressed the outlook of the Jena romantics.

The concept of intellectual intuition, allied with aesthetic intuition, became one of Schelling's central concepts. In the philosophy of identity he viewed intellectual intuition as no longer the self-contemplation of the ego, as he had done earlier following Fichte's example, but as a form of self-contemplation of the Absolute, which was presented now as the identity of subject and object. This idealist teaching was developed most clearly in his dialogue *Bruno, or the Divine and Natural Principle of Things* (1802). Since the Absolute is the identity of the subjective and the objective, it is neither spirit nor nature, according to Schelling, but an indifference of both (like the point of indifference of the poles in the center of a magnet)—a nothing that contains the possibility of all determinations. The complete development or realization of these potencies, according to Schelling, is the universe; it is the identity of the absolute organism and the absolute work of art. The Absolute engenders the universe to the same extent that it creates the universe as an artist would: emanation and creation merge here in the indifference of oppositions. In this system of aesthetic pantheism, which goes back to Neoplatonism, Schelling was close to the pantheism of German mysticism (Eckhart).

In his *Philosophy and Religion* (1804), Schelling raised questions that led him beyond the philosophy of identity: How and by virtue of what was the world born out of the Absolute? Why was that balance of the ideal and the real that exists at the point of indifference disturbed, with the result that the world emerged? In *Of Human Freedom* (1809; Russian translation, 1908), Schelling stated that the genesis of the world from the Absolute cannot be explained rationally; it is an irrational primary fact rooted not in reason but in will and its accompanying freedom. Following J. Boehme and F. X. von Baader, Schelling distinguishes in god both god himself and his indefinable ground, which he calls the abyss, or the ungrounded, and which is something unreasonable and dark—unconscious will. It is because of the presence of this dark ground that the division of the Absolute occurs, an act of assertion of free will, a separation from the universal divine principle—an irrational fall that is impossible to understand using the laws of reason and nature. The act of the fall is a supratemporal act; unconscious will operates before any consciousness, and on a metaphysical level man is guilty even at the moment of his birth. The expiation of this original guilt and reunion with the Absolute, and thereby the reunion of the Absolute itself, is, according to Schelling, the goal of history.

Insofar as will as a primordial irrational desire is an inscrutable primary fact, it cannot be an object of philosophy comprehended as a rational deduction of everything real from an initial principle. Calling this rationalistic philosophy (including his philosophy of identity and the philosophy of Hegel) negative, Schelling considered it necessary to supplement it with a positive philosophy that examines the primary fact—irrational will. The latter is comprehended empirically, in an experience identified by Schelling with mythology and religion, in which the revelation of god was given to consciousness in history. In this philosophy of revelation, Schelling essentially left philosophy proper and approached theosophy and mysticism. The lectures on positive philosophy, or the philosophy of revelation, that he began in 1841 in Berlin were not a success with audiences; the young F. Engels, for example, wrote a series of pamphlets against Schelling.

Schelling's philosophy greatly influenced European thought of the 19th and 20th centuries; as European thought passed through its stages of development, different aspects of Schelling's teaching were accepted. His effect on Russian philosophy was significant—through the natural philosophers D. M. Vellanskii, M. G. Pavlov, and M. A. Maksimovich, the Moscow Liubomudry circle (V. F. Odoevskii, D. V. Venevitinov, and A. I. Galich), the Slavophiles, and P. Ia. Chaadaev, who was personally acquainted with and corresponded with Schelling. In the 20th century Schelling's irrationalistic ideas were developed in the philosophy of existentialism. The founders of Marxism valued Schelling first and foremost for the dialectics of his philosophy of nature and for his teaching about development, that is, those elements that exerted the greatest influence on the formation of Hegel's philosophy.

SCHERER, WILHELM. Born Apr. 26, 1841, in Schönborn, Austria; died Aug. 6, 1886, in Berlin. German philologist.

Scherer graduated from the University of Vienna in 1864. He became a professor at Vienna in 1868, at the Kaiser Wilhelm University (University of Strasbourg) in 1872, and at the University of Berlin in 1877. The leader of a school of positivist literary scholars, he advocated renunciation of the traditions of idealist metaphysics. Scherer sought to apply the rigorous methods of science to the humanities and to introduce the historical descriptive method into comparative and genetic philology. His theory governed the development of Germanic philology in Germany for many years. Scherer also studied the history of the German language.

SCHERFIG, HANS. Born Apr. 8, 1905, in Copenhagen. Danish satirical writer and artist. Member of the Communist Party of Denmark.

In the novel *The Dead Man* (1937; Russian translation, 1972), Scherfig examines the problems of art in a capitalist society. The satiric novels *The Missing Official* (1938; Russian translation, 1956) and *A Wasted Spring* (1940; Russian translation, 1960) and the antifascist novel *The Idealists* (1945) deal with the fate of the bourgeois intelligentsia. Disguising his works as detective novels, Scherfig denounces social injustice, bourgeois hypocrisy, and unfairness in the education system and the state bureaucracy.

On June 22, 1941, Scherfig was arrested by the Hitlerite occupiers; he escaped in 1943 and went underground until the end of the war. His novel *The Scorpion* (1953; Russian translation, 1956) is directed against the corruption of the upper circles in postwar Denmark. He depicted World War II in the novel *Frydenholm* (1962; Russian translation, 1965). In the novella *The Missing Monkey* (1964; Russian translation, 1965), Scherfig sharply criticized contemporary modernistic art. Scherfig is the author of many works on literature and art, including *On the Way to the Constellation Aquarius* (1951) and *Three Poets* (1963), which deals with N. Grieg, B. Brecht, and H. R. Kirk. He has contributed to the Communist press. He is the author of *A Journey Through the Soviet Union* (1951) and travel essays on the socialist countries.

SCHEUCHZER, JOHANN JAKOB. Born Aug. 2, 1672, in Zürich; died there June 23, 1733. Swiss naturalist.

Scheuchzer studied in Altdorf and Utrecht. In 1696 he became assistant municipal physician in Zürich, later assuming the head position. In 1710 he became a professor of mathematics at the *Gymnasium* in Zürich, and in 1733, a professor of physics.

Scheuchzer studied the glaciers and geological structure of the Alps. He published a number of works on paleontology and geology. In his theoretical ideas he was an adherent of diluvianism: he believed organisms that were extinct had perished during "the flood." He described many different species of fossil plants and animals and was one of the first to note the plant origin of coal. In 1700 he found the skeleton of a large fossil salamander (*Andrias Scheuchzeri* Cuvier) and mistook it for a human skeleton.

Scheuchzer was a member of the Leopoldina German Academy of Naturalists (1697).

SCHEUCHZERIA, a genus of perennial herbs of the family Scheuchzeriaceae. The plants have a climbing rhizome. The leaves, which are situated high on the stem, are two-rowed and linear. The leaf sheaths are enlarged. The small greenish bisexual flowers are in a loose racemose inflorescence. The perianth consists of six leaflets arranged in two circles. The fruit is usually trifoliate, with three bulging fruitlets widely spaced apart.

There are one or two species, distributed in cold and temperate belts of the northern hemisphere. The USSR has one species, *S. palustris*, which grows everywhere but in the southern European portion, in Siberia, and in the Far East. The plant occurs in very damp sphagnum swamps, on swampy peat shores of reservoirs, and in floating masses of vegetation. The *Scheuchzeria* aid in the formation of peat.

SCHICK TEST, a skin test used to determine human susceptibility to diphtheria; one of the allergy-based diagnostic tests, proposed in 1913 by the Austrian pediatrician B. Schick. Dilute active diphtheria toxin is injected into the skin. Local inflammation (reddening, edema) develops three to four days later, and an individual's reaction is evaluated from the severity of the inflammation. The Schick test is used to determine which individuals, primarily children, should be vaccinated against diphtheria.
[29–1183–1]

SCHIFF, HUGO. Born Apr. 26, 1834, in Frankfurt am Main; died Sept. 8, 1915, in Florence. Italian chemist. German by nationality.

A student of F. Wöhler, Schiff was a privatdocent at the University of Bern (1857). He later emigrated to Italy, where he worked in Florence from 1863 to 1876 and from 1879 to 1915. From 1876 to 1879 he was a professor at the University of Turin.

Schiff's main works were devoted to organic chemistry. Schiff discovered the condensation reaction of aromatic amines with aldehydes (1864) and investigated the products of the reaction, which have come to be called Schiff bases. He synthesized populin (1868) and digallic, or tannic, acid (1873). He proposed qualitative reactions for aldehydes (with fuchsin sulfurous acid; called the Schiff reaction), urea, and pentosanes. Schiff invented the azotometer (or nitrometer), a device for determining nitrogen according to the method proposed by J. B. Dumas.

[29–1242–2]

SCHIFF BASE, any one of a class of organic compounds with the general formula $RR'C{=}NR''$, where R and R′ represent hydrogen, an alkyl, or an aryl and R″ is an alkyl or aryl; in the latter case, Schiff bases are also called anils.

Schiff bases are crystalline or oily substances that are insoluble in water and soluble in organic solvents. They are weak bases, forming salts with acids in an anhydrous medium; in aqueous acid solutions they undergo hydrolysis to yield an amine and aldehyde. The majority of Schiff bases are stable in alkaline solutions. Schiff bases undergo hydrogenation to give secondary amines ($RR'CH{-}NHR''$) and add on many compounds containing mobile hydrogen, such as β-dicarbonyl compounds, ketones, and imines. They are produced mainly by the condensation of aldehydes or ketones with primary amines.

The reaction was first completed by H. Schiff in 1864 (hence the name of the compounds). Schiff bases are valuable intermediate products of organic synthesis, for example, in the preparation of secondary amines and various heterocyclic compounds. The Schiff bases known as azomethine dyes are used for dyeing acetate and synthetic fibers; they are also used in color photography to reduce the photosensitivity of photographic emulsions.
[29–1242–3]

SCHILLER, FERDINAND CANNING SCOTT. Born Aug. 16, 1864, near Altona; died Aug. 6, 1937, in Los Angeles. British idealist philosopher, representative of pragmatism.

Schiller taught at Oxford University from 1903 to 1926. He became a professor at the University of Southern California in the USA in 1929. Schiller's version of pragmatism, called humanism, is based on the premise that knowledge as a product of human activity reproduces only the human element of a reality dependent on human activity. Unlike W. James, Schiller saw the criterion of

truth not in the sensible, but only in the good (useful) consequences of an action. Schiller's metaphysics was a combination of pragmatic subjective idealism and voluntarism, personalism, and teleology (god, according to Schiller, is the driving force of development, a reasonable and personal spirit). In the sociopolitical sphere, Schiller took an anticommunist stand and sympathized with fascism.

A. S. BOGOMOLOV [29–1191–1]

SCHILLER, JOHANN CHRISTIAN FRIEDRICH VON. Born Nov. 10, 1759, in Marbach am Neckar; died May 9, 1805, in Weimar. German poet, dramatist, aesthetician, and historian. An outstanding representative of the Enlightenment in Germany and one of the founders of modern German literature.

Schiller's father was initially an assistant army surgeon and later an officer in the service of Duke Karl Eugen of Württemberg. The writer was brought up in a pious atmosphere that was reflected in his early poetry. After graduating from a Latin school in Ludwigsburg in 1772, he was enrolled at the order of the duke of Württemberg in a military school (Karlsschule), later renamed an academy. He studied first in the law division and then in the medical division. At the academy Schiller became acquainted with the moralistic philosophy of A. Ferguson and Shaftesbury, with the ideas of the English and French Enlightenment philosophers Locke, Montesquieu, Voltaire, and Rousseau, and with the works of Shakespeare, Lessing, and the *Sturm und Drang* poets. Schiller's social and political views were also influenced by German antifeudal journalism and by the liberation movement in America. After graduating from the academy in 1780, he was appointed a regimental surgeon in Stuttgart.

By the time of his graduation, Schiller had completed his first tragedy, *The Robbers* (published 1781, staged 1782), in which he protested against the feudal system in Germany. The main hero tends to make pronouncements for effect, and the ending compromises the ideals voiced in the play. Nevertheless, the tragedy was subsequently viewed as a militant revolutionary play. While in Stuttgart, Schiller published the *Anthology for the Year 1782*, a collection of poems most of which were written by himself. He also wrote *Fiesco, or the Genoese Conspiracy* (1783), a tragedy based on Italian Renaissance history.

For absenting himself from his regiment without leave in order to attend a performance of *The Robbers* in Mannheim, Schiller was arrested and forbidden to write on any subject but medicine. This restriction forced him to flee from the duke's domain. He settled first in the hamlet of Bauerbach, where he completed the drama *Luise Millerin* (subsequently called *Love and Intrigue*), and then in Mannheim. He moved to Leipzig in 1785 and then to Dresden.

Schiller's early dramas and lyric works raised the *Sturm und Drang* movement to a new level by making it more purposeful and socially effective. *Love and Intrigue* (1784), which F. Engels called the first politically tendentious German drama, is of especially great importance. The play expresses the main social contradiction of Schiller's time, that between the disfranchised people and the ruling aristocracy. This bourgeois tragedy (as Schiller, in keeping with the spirit of Enlightenment literature, defined the play's genre) contained the outlines of a great social and philosophical tragedy that Schiller soon developed on a historical theme. From 1783 to 1787 he worked on *Don Carlos*, a drama based on 16th-century Spanish history. Originally conceived as a domestic drama about the Spanish infante, the play was changed into a tragedy dealing with the Marquis of Posa, a social reformer and citizen of the universe. In the final version Schiller used iambic pentameter rather than prose; he defined the genre as a dramatic poem. The tragedy shows the irreconcilable conflict between the ruling absolutism and the ideal of reason and freedom. Posa's fate anticipates the tragedy of the noble idealist and enthusiast that Schiller later formulated theoretically and gave literary embodiment to in his poetry.

Schiller's move to Weimar in 1787 opened the new phase in his work that had been promised by *Don Carlos*. While reviewing the works and the artistic principles of the *Sturm und Drang* movement, he began studying history, philosophy, and aesthetics. In 1788 he became the editor of a series of books under the title *The History of Remarkable Uprisings and Conspiracies*. That same year he wrote *The History of the Defection of the United Netherlands From the Spanish Empire*, in which he interpreted the liberation movement of the Dutch people as a harbinger of the struggle between the old world and the ideals of the Enlightenment. Only the first volume of the work was published.

In 1789, with the assistance of Goethe, with whom he had become acquainted in 1788, Schiller was appointed extraordinary professor of history at the University of Jena. At Jena he delivered an introductory lecture entitled *What Is Universal History and Why Do We Study It?* In 1793 he published *The History of the Thirty Years' War* and several articles on universal history. By this time he had become an adherent of the philosophy of I. Kant, whose influence can be seen in Schiller's works on aesthetics, such as *On Tragic Art* (1792), *On Grace and Dignity* (1793), *Letters on the Aesthetic Education of Man* (1795), and *On Naïve and Sentimental Poetry* (1795–96).

In his study of universal history, Schiller noted progress in the development of society, although society had not rid itself of barbarism and slavery. His reflections on the historical fate of mankind intensified his tragic perception of the world. Schiller welcomed the French Revolution, and in 1792 the Convention named him an honorary citizen of the French Republic. He was alarmed, however, by the Jacobin dictatorship. While approving the overthrow of the feudal system, he condemned the execution of Louis XVI and viewed it as an act of violence, which he now rejected in any form.

Having repudiated revolutionary methods of social change, Schiller formulated an extensive program of aesthetic education, believing that "the way to freedom is only through beauty" and that the mission of art is gradually to prepare corrupted and enslaved contemporary man for the rational social relations of the future. In accordance with this aesthetic-political program, Schiller advocated the principles of idealization that had enabled artists in the classical era to attain unsurpassed heights. He was a founder of Weimar classicism, and its tenets were reflected in his lyric poems of the late 1780's and the 1790's, such as "Ode to Joy," "The Gods of Greece" and "The Artists."

According to Schiller, his friendship with Goethe was the equivalent of a whole epoch in his development. In their correspondence Schiller and Goethe posed the cardinal aesthetic problems of their time and extensively discussed their works in progress. They jointly wrote the *Xenien* (literally, "gifts for guests"), a cycle of epigrams that was directed against shallow rationalism and philistinism in literature and the theater and against the early German romantics. The friendship with Goethe contributed to a new upsurge in Schiller's art. From 1795 to 1798 he edited the journal *Die Horen* and, in competition with Goethe, wrote the ballads "The Diver" ("The Goblet" in V. A. Zhukovskii's translation), "The Glove," "The Ring of Polycrates," and "The Cranes of Ibycus." In "The Song of the Bell" (1799) he again condemned violence, which leads to anarchy, and at the same time glorified the joy of creative work and concord among men. Schiller's views on aesthetics also changed; he concluded that there was a radical difference between ancient poetry, which was "naïve" and objective, and modern poetry, which is "sentimental" and subjective. He believed that contemporary literature should combine the ideal and the real.

In Schiller's mature work the main conflict depicted is that be-

tween harsh reality and the Enlightenment ideal of the free organization of society. This theme is developed in his poem "Ideal and Life" (1795). Schiller's later tragedies deal with turning points in history, which are rendered in a stylized and at times conventional manner. These works reveal the tragic state of man in his conflict with objective historical necessity. This basic tragic conflict is complicated in Schiller's plays by other social, political, ethical, and psychological clashes and problems, but as a philosophical conflict it determines the structure of the tragedies.

In 1791, Schiller conceived the idea of the tragedy *Wallenstein* (published 1800), which in the process of writing became a trilogy consisting of *Wallenstein's Camp* (staged 1798), *The Piccolomini* (staged 1799), and *The Death of Wallenstein* (staged 1799). The trilogy was based on the Thirty Years' War of 1618–48. Wallenstein's contradictory personality is revealed through a complex chain of political and psychological conflicts. Schiller's *Maria Stuart* (1801) was based on 16th-century English history. In this play the most important political problem of the Europe of his time—the relationship between the individual and the new, bourgeois state—acquired an enormous tragic resonance owing to his masterly portrayal of the heroine's character. In the "romantic tragedy" *The Maid of Orleans* (1801), Schiller glorified the French national heroine Joan of Arc and combined a patriotic theme with the heroine's ethical conflict.

The drama *The Bride of Messina* (1803) was an original attempt at reviving classical forms and the concern with fate characteristic of classical tragedy. In *Wilhelm Tell* (1804), a drama about the legendary Swiss national hero, Schiller arrived at a justification of revolutionary action, although this justification was not always consistent. The main themes of the drama are the people's influence on the course of history and the consequent necessity for the hero to be linked to the people. In the last months of his life Schiller worked on the tragedy *Demetrius*, which was based on Russian history; his sudden death left the work unfinished.

One of the greatest tragedians of world literature, Schiller created a special type of drama, one in which ideas were declaimed in poetic forms. The traditions of this type of drama influenced the dramatugy of the Junges Deutschland movement, as seen in the works of K. Gutzkow. Other writers influenced to a greater or lesser degree by these traditions include F. Hebbel, G. Hauptmann, H. Ibsen, and, in the 20th century, B. Shaw and B. Brecht.

Schiller was known in Russia as early as the 1790's; translations from his works were made by such writers as N. I. Gnedich, G. R. Derzhavin, V. A. Zhukovskii (whose translations became classics), A. S. Pushkin, M. Iu. Lermontov, F. I. Tiutchev, and A. A. Fet. One of the most popular foreign writers, he was highly valued by V. G. Belinskii, A. I. Herzen, I. S. Turgenev, and L. N. Tolstoy; there are direct echoes of Schiller's works in F. M. Dostoevsky's novels. Schiller's popularity in Russia increased especially during the Revolution of 1905–07 and after the Great October Revolution of 1917; his plays hold a firm place in the repertoire of Soviet theaters.

The works of this great humanist and herald of the ideals of freedom and universal brotherhood have been studied in depth and popularized in the German Democratic Republic, especially by the National Museum of German Classical Literature in Weimar. Soviet scholars have made a considerable contribution to the study of Schiller's legacy.

SCHILLER, LEON (real surname, de Schildenfeld). Born Mar. 14, 1887, in Kraków; died Mar. 25, 1954, in Warsaw. Polish theatrical figure, director, and pedagogue. Member of the Polish United Workers' Party from 1948.

Schiller worked in a number of theaters in Warsaw: he was a director at the Teatr Polski from 1917 to 1920 and at the Reduta Theater from 1922 to 1924; together with W. Horzyca and A. Zelwerowicz he ran the W. Bogusławski Theater from 1924 to 1926. During the 1930's, Schiller headed theaters in Poznań, Łódź, and Lwów (L'vov). His productions, which included Mickiewicz's *Dziady*, Słowacki's *Kordian*, Krasiński's *The Undivine Comedy*, and Brecht's *Threepenny Opera*, were marked by revolutionary romanticism and conveyed a protest against the social injustice of the bourgeois world.

Schiller was in charge of the Teatr Wojska Polskiego in Łódź from 1946 to 1949 and of the Teatr Polski in 1949 and 1950. He played a decisive role in the development of 20th-century Polish theater and molded the aesthetic principles upon which the Polish monumental style of theater is based. Relying heavily on the traditions of Polish romanticism, he endowed his productions with strong social overtones. Schiller undertook pedagogical work in 1933. He founded the quarterly *Pamiętnik teatralny* in 1952.

Schiller was a deputy to the Sejm from 1947 to 1952. He served as president of the Association of Polish Theater and Film Artists from 1950 to 1954. Schiller was awarded the State Prize of the Polish People's Republic in 1948.

SCHILLING, the monetary unit of Austria; equal to 100 groschen. Introduced in 1925 to replace the crown, the schilling was replaced by the reichsmark in 1938 but reintroduced in 1945. According to the rate of exchange set by the State Bank of the USSR in January 1978, 100 schillings = 4.55 rubles. [29–1192–1]

SCHILTBERGER, JOHANN (also Hans Schiltberger). Born 1380; died not earlier than 1438. Bavarian soldier.

Schiltberger was captured by the Turks at the battle of Nikopol in Bulgaria. His *Book of Travels* told of his wanderings in Asia Minor, Egypt, Middle Asia, Siberia, and the Caucasus. Schiltberger's work was the earliest European description of Siberia and northern Asia.

SCHIMMELPENNINCK, RUTGER JAN. Born Oct. 31, 1761, in Deventer; died Mar. 25, 1825, in Amsterdam. Dutch state figure; a lawyer by education and profession.

A moderate republican and a supporter of the French Revolution, Schimmelpenninck helped found the Batavian Republic in 1795. Between 1798 and 1805 he served intermittently as its ambassador in Paris. In November 1805 he was appointed by Napoleon I to the post of grand pensionary, or head of government, of the Batavian Republic. He opposed Napoleon's efforts to turn the republic into a kingdom and was forced to resign in 1806. Schimmelpenninck was a member of the Dutch First Chamber from 1815 to 1821. [29–1202–1]

SCHIMPER, ANDREAS FRANZ WILHELM. Born May 12, 1856, in Strasbourg; died Sept. 9, 1901, in Basel. German botanist.

Schimper, the son of W. P. Schimper, graduated from the University of Strasbourg in 1878. He became a professor at the University of Bonn in 1886 and at the University of Basel in 1898. He traveled frequently to study tropical plants. Schimper substantiated and developed the ecological-physiological school in plant geography and distinguished five types of vegetation based on the interrelation of physiology and geography. He elucidated the genetic links between various types of plastids and studied the formation of starch grains.

SCHIMPER, WILHELM PHILIPP. Born Jan. 12, 1808, in Dossenheim; died Mar. 20, 1880, in Strasbourg. German botanist.

Schimper graduated from the University of Strasbourg in 1832. He worked at the Strasbourg Museum of Natural History from 1835, becoming its director in 1866. In 1862 he became a professor at the University of Strasbourg. His main works are on the flora of European mosses and on fossil plants. Schimper was one of the founders of paleobotany. In 1854 he became a member of the French Academy of Sciences.

SCHINKEL, KARL FRIEDRICH. Born Mar. 13, 1781, in Neuruppin, Brandenburg; died Oct. 9, 1841, in Berlin. German architect, painter, and graphic artist.

Schinkel studied at the Berlin Academy of Architecture under F. Gilly from 1798 to 1800. He worked mainly in Berlin. He initially concentrated on painting and the graphic arts, producing landscapes, panoramas, works of stage design, drawings, and lithographs in the romantic style.

The most outstanding representative of late classicism in 19th-century German architecture, Schinkel strove for laconically monumental composition. His works include the Neue Wache (now a monument to the victims of fascism and militarism), the Drama Theater, and the Altes Museum, all in Berlin. He also revealed romantic tendencies in his pseudo-Gothic buildings, including a chapel in Petergof (1831–33). In the last years of his life, renouncing the forms of classicism and the Gothic, he anticipated the principles of rationalism, for example, in the Academy of Architecture in Berlin (1831–35). He also was an architectural theorist.

SCHIRMACHER PONDS, an ice-free section of the coastland of Queen Maud Land, in Eastern Antarctica. Separated from the Lazarev Sea by an ice shelf that is approximately 80 km wide, Schirmacher Ponds has an area of approximately 32 sq km and rises to an elevation of 221 m. The rounded hills of the region are separated by elongated hollows, and there are numerous lakes. Along the northern edge of the region there are lagoons that communicate with the sea beneath the ice shelf. The region was discovered in 1939 by a German expedition led by A. Ritscher and was named in honor of a member of the party, the pilot R. Schirmacher. The Soviet antarctic station Novolazarevskaia has been operating in the eastern part of Schirmacher Ponds since 1961. [29–1227–1]

SCHIRRA, WALTER MARTY, JR. Born Mar. 12, 1923, in Hackensack, N.J. US pilot and astronaut. Captain in the navy.

Schirra studied at the Newark College of Engineering in 1940 and 1941. He served in naval air units after graduating in 1945 from the US Naval Academy at Annapolis, Md. Schirra also graduated from the Naval Air Safety Officer School at the University of Southern California and the test pilot training school at the Naval Air Test Center at Patuxent River, Md.

Schirra became a member of the National Aeronautics and Space Administration astronaut corps in 1959. On Oct. 3, 1962, he flew six orbits around the earth in a Mercury capsule. The flight, designated MA-8, lasted 9 hr 13 min. On Dec. 15 and 16, 1965, as command pilot, Schirra flew with T. Stafford aboard the Gemini 6 spacecraft. Gemini 6 achieved rendezvous on December 15 with the Gemini 7 craft, which had been launched into orbit on December 4. During formation flying that lasted 5.5 hr, the ships maneuvered to within 1 m of each other. The total flight time was 25 hr 51 min.

From Oct. 11 to Oct. 22, 1968, with W. Cunningham and D. Eisele aboard, Schirra completed 163 orbits of the earth as commander of the Apollo 7 spacecraft. During the flight, which lasted 10 days 20 hr 9 min, Schirra conducted the first flight test of the Apollo command module. Schirra's three flights gave him a total of 295 hr 13 min of flying time in space. [29–1237–2]

SCHISTOSOMIASIS, any one of several diseases of humans and animals caused by helminths of the family Schistosomatidae of the class Trematoda.

Schistosomiases of humans occur mainly in tropical countries. The causative agents belong to the genus *Schistosoma*, whose females deposit eggs in the small blood vessels of the urinary bladder and intestine. After entering these organs, the eggs are excreted with urine or feces. Larvae (miracidia) emerge from the eggs after they reach water and are ingested by mollusks, in which they reproduce and develop. The cycle is completed with the emergence of larvae with tails (cercariae) in the water. The cercariae penetrate the human body through the skin and mucous membranes. Individuals become infected after working or swimming in bodies of water contaminated by the urine and feces of persons suffering from schistosomiasis or after drinking water from such bodies of water.

Skin rashes, itching, and sometimes fever occur in the early stage of schistosomiasis. If the genitalia and intestine are affected

(bilharziasis), the patient feels a sharp pain upon urination, the urine becomes tinged with blood, and chronic colitis, with mucus and blood appearing in the feces, develops. Schistosomiasis is treated with antimony agents, for example, Anthiomaline (or anthiolimine); it is also treated with Ambilhar (or niridazole). The disease can be prevented by protecting lakes and streams from pollution, by banning swimming in stagnant or slow-flowing water in areas where schistosomiasis is endemic, and by boiling drinking water or filtering it through cloth.

N. N. PLOTNIKOV [29–1239–5]

SCHIZOGNATHISM, a type of structure of the palate in birds, in which the maxillopalatals are not united with one another or with the vomer, the posterior part of which is bifurcated, and the anterior part, pointed. Schizognathism, a form of neognathism, is characteristic of Procellariiformes, Galliformes, Columbiformes, and the majority of Limicolae. [29–1179–2]

SCHIZOGONY, multiple asexual reproduction in protozoans, including foraminiferans, trypanosomes, and sporozoans, as well as in some algae. In schizogony, the nucleus of the maternal individual undergoes a succession of rapid divisions into several nuclei and breaks down into the corresponding number of mononuclear cells (merozoites). The sexual process begins after several asexual generations. Sporozoan merozoites penetrate the host cells and give rise to gametocytes, from which gametes are formed. [29–1179–3]

SCHIZOID, a constitutionally and genetically determined type of personality characterized by autism (that is, preoccupation with the self and alienation from the external world), emotional coldness combined with marked vulnerability, and the predominance of abstract thinking. It is often associated with an asthenic body build. [29–1179–4]

SCHIZOPHRENIA, the commonest mental illness, characterized by the variety of its manifestations and by its tendency to become chronic.

As early as the 17th century, T. Willis observed adolescents who lost their childhood talents and became "grumbling fools" as young adults. In 1857 the French psychiatrist B. A. Morel identified dementia praecox as a form of "hereditary degeneration." In the 1860's and 1870's the German psychiatrists K. L. Kahlbaum and E. Hecker described hebephrenia and catatonia. In 1888 the French psychiatrist V. Magnan identified the chronic hallucinatory-delusional psychoses that end in apathy and feeblemindedness. In 1898, E. Kraepelin classified these forms under the single heading of dementia praecox. E. Bleuler considered the splitting, or breakdown, of the unity of the psyche to be the most important symptom of the disease, and in 1911 he proposed that it be called schizophrenia. Bleuler, however, regarded schizophrenia—as many subsequent researchers did—only as a group of related diseases.

Progress in the study of schizophrenia is associated with the names of such Russian psychiatrists as V. Kh. Kandinskii, S. S. Korsakov, and P. B. Gannushkin. The different manifestations and varying course of schizophrenia were responsible for the lack of uniformity in nosologic definitions of the disease. In France, only the malignant form (that is, process schizophrenia) is regarded as schizophrenia, whereas in Great Britain and in the Scandinavian countries most forms of schizophrenia are treated as constitutionally or psychogenically determined separate psychoses. Some investigators divide this disorder into primary (or genuine) and symptomatic schizophrenia.

The causes of schizophrenia and the mechanisms of its development are still unclear. Most investigators consider it an endogenous disease in which hereditary predisposition is a factor. The importance of heredity in this respect has been confirmed by research studies of twins affected with schizophrenia. The hereditary factor varies in different forms of the disease. When the disease follows a constant course, members of the patient's family often show symptoms of a deep schizoid psychopathy. In cases of intermittent bouts of schizophrenia, this form of the disease often develops in the patient's close relatives as well. However, schizophrenia is not classified as one of the hereditary diseases proper; compared to the latter, it is far more prevalent, affecting approximately 0.8 percent of the population.

Studies of higher nervous activity in schizophrenics show the presence of protective inhibition (in the form of hypnotic phases) and foci of sluggish excitation. Electroencephalography and quantitative analysis are used in order to determine the abnormalities in the brain's electrical activity that are characteristic of schizophrenia. Biological and biochemical studies have shown that immunological and other changes take place and that such changes vary with the form of schizophrenia. Neurochemical data indicate that in schizophrenia the metabolism of biogenic amines and enzymes is impaired. According to some investigators, the histological changes that occur in schizophrenia involve injury to the cerebral cortex; according to others, injury to the subcortical region.

Schizophrenia is usually classified according to the predominant symptoms or the specific course of the disease. To a greater or lesser degree, all forms of schizophrenia are progressive. According to the course of the disease, two basic types are distinguished—unintermittent and intermittent schizophrenia.

Unintermittent schizophrenia. Unintermittent schizophrenia is marked from its very onset by steadily intensifying disturbances (as manifested in reduced mental functioning) combined with monotonous "productive" symptoms, such as hallucinations. This type is subdivided into process, progressive, and nonprogressive schizophrenia.

Process schizophrenia usually develops in teen-agers and young adults and is generally known as hebephrenia. It is characterized by steadily progressive inactivity, emotional hypesthesia, and regressive behavior, accompanied by diverse but rudimentary productive symptoms. When it occurs in childhood, this form of schizophrenia (known as pseudo-oligophrenia) results in mental retardation.

Progressive schizophrenia is manifested in the form of a paranoid syndrome, which includes paranoia and paraphrenia; it usually occurs after the age of 30. It is marked by systematized delusions (for example, hypochondria or delusions of persecution or grandeur), combined with manifestations of psychic automatism—what is known as the Clérambault-Kandinskii syndrome, named after V. Kh. Kandinskii and the French psychiatrist G. de Clérambault (1872–1934); this consists of the feeling of being forcibly controlled by an outside influence and estrangement from one's own mental activity, ending with paraphrenia. In some cases the delusions and hallucinations coexist with proper behavior and the ability to continue working; this is known as monomania or partial insanity, as it was called by 19th-century psychiatrists. Sometimes the disease does not develop beyond the stage of systematized delusions (paranoid schizophrenia).

Nonprogressive schizophrenia (also called latent, mild, pseudoneurotic, or psychopathic-like schizophrenia) is marked by the predominance of obsessions, cenesthesiopathy (vague sensations of bodily distress), manifestations of hypochrondria and hysteria combined with pronounced autism (predominance of self-centeredness and active withdrawal from the outside world), persistent asthenia, and emotional impoverishment.

Intermittent schizophrenia. Intermittent schizophrenia is characterized by the polymorphous development of various productive symptoms, such as affective delusions and dreams; mental disturbances appear only after an attack. Intermittent schizophrenia is subdivided into intermittent-progressive and periodic schizophrenia. The productive symptoms of intermittent schizophrenia, which outnumber the negative symptoms, are keenly perceptible to the senses, affective, and labile, and they are accompanied by feelings of confusion and excitation.

The clinical picture of intermittent-progressive schizophrenia is dominated by acute delusional fantasies, the automatism of the Clérambault-Kandinskii syndrome, and catatonic excitement. The vividness, plasticity, and affectivity of such disorders are less pronounced than in the case of periodic schizophrenia. Negative effects become evident after the first attack is over, sometimes growing more intense after each successive attack. The disease takes an almost unintermittent course and represents an intermediate variety between intermittent and unintermittent schiz-

ophrenia. In other cases, the negative manifestations occurring after the first attack either remain unchanged, in spite of successive similar attacks, or grow more intense after the fourth or fifth attack or even later—that is, irregularly. It is not unusual for a single attack of schizophrenia to occur, followed by a change in personality (for example, in the form of persistent asthenia).

Periodic schizophrenia (also called recurrent or schizo-affective) is marked by excitation, confusion, affective-delusional and oneiric incidents, and minor personality changes.

Unlike progressive and process schizophrenia, the intermittent and nonprogressive forms of the disease may occur at any age. It has been established that specific forms of schizophrenia are sex-related. Process schizophrenia and unintermittently progressive schizophrenia are found more frequently in men than in women (the ratio being 3:1), whereas intermittent schizophrenia is more common in women (the ratio here being reversed). The overall incidence of the disease, however, is approximately the same among men and women.

Treatment. Treatment depends on the form of and the stage reached by the disease; it includes insulin therapy (where hypoglycemia is induced by injecting insulin), electroconvulsive therapy, occupational therapy, and psychotropic agents. Prophylactic measures are primarily directed at preventing acute manifestations of the disease and achieving more extended remission; they consist of preventive treatment—that is, small "maintenance" doses of psychotropic agents and proper working and living habits.

The high level of organization of inpatient and especially outpatient care, treatment by psychotropic agents, and occupational rehabilitation are significantly reducing the rate of permanent disability caused by schizophrenia. As research continues in this area, the opportunities for work rehabilitation are growing steadily. It is only the severe forms of schizophrenia that justify placing patients on disability, exempting them from military service, or limiting their choice of occupation. It is precisely for this reason that schizophrenia requires the kind of diagnosis known as binomial, which identifies not only the disease but also its specific form and course.

SCHLAGINTWEIT BROTHERS. German geographers and mountaineers.

Adolf Schlagintweit was born on Jan. 9, 1829, in Munich. He was executed on Aug. 26, 1857, in Kashgar, China.

Hermann Schlagintweit was born on May 13, 1826, in Munich and died there on Jan. 19, 1882.

Robert Schlagintweit was born on Oct. 27, 1833, in Munich and died on June 6, 1885, in Giessen.

From 1854 to 1857, on the initiative of A. von Humboldt and with the backing of the Prussian government and the British East India Company, the Schlagintweit brothers traveled about India and Central Asia, exploring the Deccan Plateau, the Himalayas, the Karakoram, the Kunluns, Sinkiang, and the Tibetan Highlands. Before 1853, Adolf and Hermann also explored the Alps. In 1868 and in 1880, Robert climbed mountains in the USA.

SCHLEGEL, AUGUST WILHELM VON. Born Sept. 8, 1767, in Hanover; died May 12, 1845, in Bonn. German literary historian and writer. Brother of F. von Schlegel.

A. von Schlegel studied classical philology at the University of Göttingen from 1787 to 1791. Beginning in 1818, he taught literary history at the University of Bonn and did work in Sanskrit studies. He was one of the founders of comparative linguistics. Schlegel belonged to the Jena school of German romantics. In his works, including the Berlin lectures on literature and aesthetics (1801–04, published 1884) and the Vienna lectures on dramatic art and literature (1808, published 1809–11), he gave the first systematic analysis of romanticism as a historical and aesthetic concept. In this analysis, which became famous throughout Europe, he contrasted ancient, classical aesthetics to modern, romantic aesthetics.

An outstanding theorist of artistic translation, Schlegel translated works by Dante, Calderón, and Petrarch; his translations of the plays of Shakespeare remain unsurpassed. Schlegel's own literary works, including *Poetic Works* (1811) and his dramas, were influenced by classicism.

SCHLEGEL, FRIEDRICH VON. Born Mar. 10, 1772, in Hanover; died Jan. 12, 1829, in Dresden. German critic, philologist, idealist philosopher, writer, and theorist of romanticism. Brother off A. W. von Schlegel.

F. von Schlegel studied classical philology in Leipzig. In articles written in the 1790's under the influence of J. J. Winckelmann, he viewed ancient Greek poetry as the prototype of true art and the embodiment of the objectively beautiful. He sharply criticized modern culture and art for preferring "the mannered, the characteristic, and the individual," for mixing genres, and for tirelessly striving after "the new, the piquant, and the striking" (*On the Study of Greek Poetry*, 1797).

Schlegel lived in Jena from 1796 to 1801. He published the journal *Athenaeum* with A. von Schlegel from 1798 to 1800 and formulated the basic tenets of the Jena school of romantics. In this period he extolled the romantic art of his time. He regarded Dante, Shakespeare, Cervantes, and Goethe as the greatest representatives of romantic art, which he distinguished from the classical art of antiquity. In his numerous "fragments" and aphorisms Schlegel advanced the utopian ideal of a new, universal poetry and culture that would aesthetically transform the world. The new poetry and culture would be oriented toward the "infinite plenitude of the universe" and would undergo a continuous, never-ending process of creative development. The new culture would constantly reflect upon itself and its works; it would fuse art, philosophy, science, and religion. Schlegel regarded ancient mythology as the prototype of such a fusion and dreamed of a new mythology, the beginnings of which he saw in the natural science of his day and in post-Kantian idealist philosophy (*A Conversation About Poetry*, 1800).

Associated with Schlegel's theory of a universal poetry and culture is his treatment of irony, which he viewed as an expression of the dynamism of the world and of cognition. Irony expresses a

feeling of wholeness; it impels the artist to rise above limitations imposed by the individual self, by the material represented, and by the means of representation.

According to Schlegel, the novel is an encyclopedia of the spiritual life of an individual and the highest genre of the new poetry. He regarded Goethe's *Wilhelm Meister* and Cervantes' *Don Quixote* as exemplars of the genre. Schlegel's unfinished and fragmentary novel *Lucinde* (1799), which provoked a charge of immorality, was based on a romantic theory of love and marriage as spiritual and physical union and as the harmonious mutual complementing of man and woman.

From 1802 to 1804, Schlegel lived in Paris. From 1803 to 1805 he published the journal *Europa*, which was devoted to the concept of the spiritual communality of European culture. His *Geschichte der alten und neueren Literatur* (vols. 1–2, 1813–15; English translation under the title *Lectures on the History of Literature*) continued the tradition of J. G. von Herder and played an important role in the development of romantic historicism. National literatures in this work are examined as unique entities. For Schlegel, a national literature expressed the spiritual life of its people and reflected the people's religious, philosophical, and political history.

After his conversion to Catholicism in 1808, Schlegel lived in Vienna. He took up a position in the Austrian government and worked closely with Metternich. Schlegel, who in the 1790's had favored republicanism and supported the ideals of the French Revolution, now espoused the conservative romantic ideal of a "true empire." In the journal *Concordia* (1820–23), he viewed the Austrian estate monarchy as an embodiment of this romantic ideal. In *The Philosophy of Life* (1828), *The Philosophy of History* (vols. 1–2, 1829), and *The Philosophy of Language and Speech* (1830), Schlegel developed the notion of a universal Christian philosophy. Criticizing various philosophical systems, particularly German classical idealism, as forms of divided consciousness, he maintained that the restoration of the inner wholeness of human consciousness was a prerequisite for a true philosophy of life based on the principles of Christian spiritualism. This wholeness involved the unity of all mental faculties, including reason, imagination, and will.

One of the founders of German Sanskrit studies and of comparative linguistics, Schlegel was the author of *On The Language and Wisdom of the Indians* (1808).

SCHLEICHER, AUGUST. Born Feb. 19, 1821, in Meiningen; died Dec. 6, 1868, in Jena. German linguist.

Schleicher, who became a professor at Charles University in Prague in 1850 and the University of Jena in 1857, subscribed to naturalist views on language. Influenced by C. Darwin, he regarded language as an organism that must be studied by the methods of the natural sciences. He applied Hegelian dialectics to linguistic phenomena and arranged in a triad the principal types of morphological structures in language. He advanced the notion of linguistic degradation, which involves aging, erosion, and destruction.

Schleicher was the first to recognize the need to establish general laws of linguistic development. The comparative method of linguistic study practiced by him paved the way for the neogrammarians' study of phonetic law (*see* NEOGRAMMARIAN). Schleicher's works played an important role in the development of Indo-European linguistics, whose task, in Schleicher's view, was to reconstruct the Proto-Indo-European parent language, in which he composed a fable.

Schleicher was among the first to undertake the study of languages (including Lithuanian) and dialects by consulting native speakers; he also studied the Slavic languages. In *A Compendium of the Comparative Grammars of the Indo-European Languages* (parts 1–2, 1861–62) he offered the most complete account up to that time of the Indo-European language system. Schleicher became a foreign corresponding member of the St. Petersburg Academy of Sciences in 1857.

A. A. KOROLEV [29–1285–1]

SCHLEICHER, KURT VON. Born Apr. 7, 1882, in Brandenburg; died June 30, 1934, in Neubabelsberg. German military and political figure; general.

Schleicher became an officer of the General Staff in 1913. After Germany's defeat in World War I he became a close associate of the commander of the Reichswehr, General H. von Seeckt, and took part in planning the restoration of the country's military potential. Schleicher headed an office in the Reichswehr Ministry in 1929 and served as minister for the Reichswehr in the government of F. von Papen from June to December 1932. He played an important role in relations between the leaders of the Nazi Party, on the one hand, and political authorities, the military, and representatives of monopolies, on the other.

Schleicher assumed the post of chancellor in December 1932. He sought to implement a dictatorial regime that would bring the fascists into the government on terms acceptable to various groups of monopolistic capital. His efforts, however, failed. He was forced to resign on Jan. 28, 1933, and was succeeded by Hitler on Jan. 30, 1933. Schleicher was murdered by the Gestapo during the purge known as the night of the long knives.

[29–1285–2]

SCHLEIDEN, MATTHIAS JAKOB. Born Apr. 5, 1804, in Hamburg; died June 23, 1881, in Frankfurt. German botanist and public figure.

Schleiden graduated from the University of Heidelberg in 1827. He was a professor of botany at the University of Jena between 1839 and 1862, and the director of the botanical gardens there from 1850. In 1863–64 he was a professor of anthropology at the University of Dorpat (present-day Tartu).

Schleiden, a reformer of contemporary botany, used the inductive method to criticize the philosophy of natural science and narrowly systematic methods in *The Fundamentals of Scientific Botany* (1842–43). His main works deal with plant anatomy and embryology. Schleiden substantiated the ontogenetic approach to the study of plant morphology and played an important role in the development of cell theory. He was one of the predecessors and advocates of Darwinism. In individual experiments he made a number of errors, such as his conception of the neogenesis of cells from structureless substances or of the development of the embryo from the pollen tube. Schleiden was the author of popular science books, which have been translated into Russian, and of collections of poetry.

D. V. LEBEDEV [29–1280–3]

SCHLEIERMACHER, FRIEDRICH. Born Nov. 21, 1768, in Breslau; died Feb. 12, 1834, in Berlin. German Protestant theologian and philosopher. Member of the Pietistic Herrnhut communal movement.

Schleiermacher studied at the University of Halle. He became a preacher in 1794 and served in Berlin from 1796 to 1802. He

was a professor at the University of Halle from 1804 to 1806. Returning to Berlin in 1807, Schleiermacher became a professor at the University of Berlin in 1810, and he was made secretary of the philosophy section of the Academy of Sciences in 1814. In the early 1800's he was close to the circle of Jena romantics, and in his *Confidential Writings About Schlegel's "Lucinde"* (1800) he defended F. von Schlegel's novel *Lucinde* for its depiction of feeling based on total inner freedom. In the rhapsodically enthusiastic *On Religion: Speeches to Its Cultural Despisers* (1799) and *Soliloquies* (1800), Schleiermacher presented an integrated religious and aesthetic ideology in a spirit of early romanticism; personal inner experience was posited as the basis of religion, which Schleiermacher defined as "contemplation of the universe," later as a feeling of "absolute dependence" on the eternal. He subsequently published a series of systematic works on philosophy (*Dialectics*, 1804), ethics, and Protestant dogmatics. Schleiermacher produced a classic translation of Plato into German.

Schleiermacher's psychologism, his belief in the preeminent role of inner feeling in knowledge and in the inscrutability of the highest source (god) for reason, in which regard he was influenced by Pietism and F. H. Jacobi, were sharply criticized by Hegel. Schleiermacher had a great influence on liberal Protestantism of the 19th century and on the development of philosophical hermeneutics and of the history of philosophy and pedagogy in Germany.

SCHLEISSING, GEORG ADAM. Born circa 1660; died no earlier than 1694. German traveler.

Schleissing visited Russia between 1684 and 1686. He published the books *Anatomy of a Deformed Russia* (1688), *Newly Discovered Siberia* (1690), and *The Ruling Council of Two Tsars in Russia* (1694). His works contain a description of the natural conditions in Russia and of Russian cities, a sketch of the political history of the 1680's, and descriptions of life, customs, and beliefs. Schleissing also published a map of Siberia and a reproduction of the first map of Siberia, which was compiled by P. I. Godunov in 1667 but which no longer exists.

SCHLESINGER, ARTHUR MEIER, JR. Born Oct. 15, 1917, in Columbus, Ohio. American historian.

Schlesinger graduated from Harvard University in 1938. He was a professor of history at Harvard from 1954 to 1961 and later at the City University of New York. From 1961 to 1964 he served as special assistant to Presidents J. Kennedy and L. Johnson.

Schlesinger represents the bourgeois-liberal trend in contemporary American historiography. His early works—for example, *The Age of Jackson* (1945)—hailed bourgeois liberalism as the moving force of social progress. Schlesinger's expression of this viewpoint took on a clearly anticommunist coloration in his works of the late 1940's and 1950's (*Vital Center*, 1949). Since the late 1950's Schlesinger has been developing, in his biographies and other historical works (*The Age of Roosevelt*), the concept of "democratic progress," theorizing that the USA's ability to resolve its differences, characteristic of the country throughout its history, has supposedly made possible the transformation of American society into one of "social justice." During the 1960's Schlesinger criticized the escalation of American aggression in Vietnam.

SCHLESINGER, FRANK. Born May 11, 1871, in New York; died July 10, 1943, in Connecticut. American astronomer.

Schlesinger's principal works dealt with photographic astrometry. He developed a technique for determining stellar parallaxes and compiled a number of catalogs of stellar positions that were determined with wide-angle astrographs designed after his idea.

SCHLESINGER, MAX. Born 1904; died Feb. 4, 1937, in London. Hungarian biochemist. One of the founders of the molecular biology of viruses.

Schlesinger graduated from the University of Budapest. Beginning in 1931, he was a researcher at the Institute of Colloids in Frankfurt am Main. After the Nazis came to power, Schlesinger emigrated to Great Britain, where he settled in London. His main works dealt with the chemical composition and physicochemical properties of bacterial viruses—bacteriophages. Schlesinger was the first to obtain a pure culture of the bacteriophage WLL of the colon bacillus (1933); he did this by passing a suspension of the bacteriophage through a colloidal filter with a graduated range of pores and then precipitating it in an ultracentrifuge. He was also able to measure the size of the bacteriophage particles. Schlesinger studied the mechanism of adsorption of bacteriophages on the host cell and determined the adsorptive capacity of bacterial cells. He was the first to establish (1934) the nucleoprotein nature of viruses, showing that bacteriophages consist of approximately equal amounts of protein and nucleic acid. In 1936 he found that the latter produces a positive Feulgen reaction to thymonucleic acid (or deoxyribonucleic acid) and that a bacteriophage is a deoxyribonucleoprotein chemically similar to a chromosome.
IA. A. PARNES [29–1280–1]

SCHLESWIG, a historical region on the southern Jutland Peninsula, north of the Eider River. In the Middle Ages, Schleswig became an object of contention between the Frankish (and later German) kings and the rulers of Denmark. Beginning in the early 12th century it was governed by Danish princes holding the title of duke. In 1386, as a Danish *lehn*, Schleswig passed to the German nobility of Holstein County. [29–1278–1]

SCHLESWIG-HOLSTEIN, a *Land* (state) in the northern part of the Federal Republic of Germany. Area, 15,700 sq km. Population, 2,600,000 (1975). The capital is Kiel.

An island chain that includes the North Frisian Islands runs along the North Sea coast of Schleswig-Holstein, whose Baltic

coast is indented by bays, including those of Lübeck and Kiel, and by inlets. Located on the Jutland Peninsula and the North German Lowland, Schleswig-Holstein is hilly in the east and southeast and rises to an elevation of 164 m.

The economy of Schleswig-Holstein is dominated by the industrial and agricultural sectors. The *Land* accounted for 3.4 percent of the gross national output of the Federal Republic of Germany in 1974. Industry produces approximately 33 percent of the gross output of Schleswig-Holstein, and agriculture, 6.6 percent. Shipbuilding in the region accounts for almost one-third of the country's tonnage of oceangoing vessels, and 55,000 tons of fish were caught commercially off the coast in 1975. Schleswig-Holstein has food-processing and textile industries, as well as a match industry that produces 20 percent of the country's matches. Other important industries include copper smelting and machine building. The principal industrial centers are Lübeck, Kiel, Rendsburg, Brunsbüttel, Heide, and Neumünster.

Farmland occupies more than 75 percent of Schleswig-Holstein. Livestock are raised for meat and dairy products. In 1975 the region had 1.5 million head of cattle and 1.6 million swine and produced 2.2 million tons of milk, 64,000 tons of butter, and 338,000 tons of meat. Grains, sugar beets, and potatoes are grown in the southeast, and vegetables are raised in the marshlands and on the island of Fehmarn. The Kiel Canal runs through Schleswig-Holstein, whose seaports include Lübeck, through which 5.6 million tons of freight were moved in 1975, and Kiel, the base for a Baltic fishing fleet. I. A. BASOVA

History. Schleswig-Holstein originally consisted of two independent areas, Schleswig and Holstein, which were united by the Holstein counts in 1386. Although Schleswig-Holstein passed to the rule of the Danish king in 1460 as a result of a personal union, Holstein, which became a duchy in 1474, formally remained a part of the Holy Roman Empire until 1806, when the empire was dissolved. The Reformation spread to Schleswig-Holstein in the mid-16th century, and, owing to the influence of the French Revolution, an extensive antifeudal movement developed in the late 18th century. Serfdom was abolished in Schleswig-Holstein in 1804. In 1806, Denmark declared full possession of Holstein. The Congress of Vienna (1814–15) recognized the right of succession of the Danish king in Schleswig-Holstein, but declared Holstein a member of the German Confederation.

The national liberation movement among the region's predominantly German population intensified in the 1830's. The outbreak of the Revolution of 1848–49 in Germany was followed by revolutionary events in Schleswig-Holstein. A provisional government established in March 1848 proclaimed the independence of Schleswig-Holstein and declared war on Denmark. The provisional government approved a draft for a constitution that F. Engels called "the most democratic [draft] ever drawn up in the German language" (K. Marx and F. Engels, *Soch.*, 2nd ed., vol. 5, pp. 422–23). With an eye to seizing Schleswig-Holstein as well as checking the growth of the revolution in Germany, Prussia entered the war against Denmark in April.

A truce concluded during the Danish-Prussian War of 1848–50 (German-Danish War of 1848–50) called for the return of Schleswig-Holstein to Denmark, the dissolution of the revolutionary provisional government, the repeal of the government's decrees, and the removal of Prussian troops from the region. These stipulations were incorporated in the London Protocol of 1852, which was signed by Great Britain, Russia, and France. Although it recognized the right of succession of the Danish monarchy, the protocol specified that Schleswig-Holstein and Denmark could be linked only through a personal union and that Holstein would remain a member of the German Confederation.

In accordance with the constitution introduced in Denmark in 1863, Schleswig was separated from Holstein and made a Danish province. This precipitated a war between Austria and Prussia, on one side, and Denmark, on the other (*see* GERMAN-DANISH WAR OF 1863–64). The war ended in Denmark's defeat; Holstein fell under Austrian rule, and Schleswig came under Prussian rule. After the Austro-Prussian War of 1866 (Seven Weeks' War), Schleswig and Holstein passed to Prussia as a single province. North Schleswig, most of whose population was Danish, was later incorporated into Denmark as a result of a plebiscite conducted in 1920 on the basis of the Peace Treaty of Versailles (1919). Schleswig-Holstein was organized as a *Land* of the Federal Republic of Germany in 1949.

SCHLICH (concentrate), a fraction of heavy minerals obtained by flushing unconsolidated natural deposits and artificially crushed rock or mineral formations. A schlich includes grains of minerals that are resistant to physical and chemical weathering and that have a density of more than 3,000 kg/m^3, for example, gold, platinum, cinnabar, cassiterite, scheelite, magnetite, zircon, and diamond.

Schlich samples are taken systematically from alluvial and diluvial deposits in the course of prospecting for placer and primary deposits of useful minerals. Schlich sampling is also used in the exploration and development of placer deposits. During the process of concentrating sands from placer deposits of gold, platinum, and other metals, what is called gray schlich, containing a significant amount of foreign minerals, is obtained first and then black schlich, which is richer in valuable metals. Schlich concentrating installations or factories, concentrating tables, and separators of various designs are used to extract valuable minerals from schlich on an industrial scale. A. M. BORSUK [29–1299–1]

SCHLICHTING, ALBERT. Dates of birth and death unknown. German nobleman from Pomerania; author of two works on Russia in the mid-16th century.

Taken prisoner by the Russians in 1564, Schlichting served as a translator and servant of the court physician A. Lensey from 1568 to 1570. In the fall of 1570 he escaped to Lithuania, where in 1571 he compiled a short report, *News From Muscovy, as Reported by the Nobleman A. Schlichting on the Life and Tyranny of His Majesty Ivan.* Schlichting later wrote *A Short Tale About the Character and Cruel Government of the Moscow Tyrant Vasil'evich*, in which he described in detail the *oprichnina* and its terror.

SCHLICK, MORITZ. Born Apr. 14, 1882, in Berlin; died June 22, 1936, in Vienna. Austrian philosopher and physicist; leading representative of the early stage of logical positivism, founder of the Vienna circle.

Schlick was a professor of philosophy and physics at the universities of Rostock from 1917 to 1920, Kiel in 1921 and 1922, and Vienna from 1922 to 1936; he was a visiting professor at Stanford University in California in 1931 and 1932. Schlick's philosophical framework was logical empiricism, at which he arrived after renouncing critical realism under the influence of R. Carnap and L. Wittgenstein. Schlick based himself on the concept of the "sensible present"—the sense experience of a cognizing individual that is incommunicable to other subjects. According to Schlick, only the structural relations of a sense experience can be the object of knowledge—relations that reproduce the order of phenomena. The so-called rational truths, including the statements of logic and mathematics, have a purely analytical character; they are tautologies that do not make it possible to penetrate into unperceived reality. According to Schlick, the problem of the cognition of the essence of existence is meaningless; the laws of nature are for him formal rules determined by the syntax of the language in which a description of nature is given.

Schlick was one of the first to formulate the principle of verification as a criterion of scientific understanding. He occupied him-

self extensively with the application of his philosophical viewpoint to specific problems of the philosophy of science (analysis of space and time, causality, probability) and of ethics.

I. S. DOBRONRAVOV [29–1288–5]

SCHLIEFFEN, ALFRED VON. Born Feb. 28, 1833, in Berlin; died there Jan. 4, 1913. German military theoretician. General field marshal (1911). Count.

Schlieffen served in the Austro-Prussian War of 1866 and the Franco-Prussian War of 1870–71 as a staff officer. He served as chief of the General Staff from 1891 to 1905, in which post he improved the training of General Staff officers. As a follower of H. Moltke the elder and one of the ideologists of German militarism, Schlieffen developed a theory for surrounding and wiping out an enemy by a decisive strike against one or two flanks. Schlieffen was the author of a plan for warfare on two fronts, against France and Russia.

WORKS
Gesammelte Schriften, vols. 1–2. Berlin, 1913.
In Russian translation:
Kanny, 2nd ed. Moscow, 1938. [29–1295–1]

SCHLIEFFEN PLAN, a draft plan for strategic deployment of the German Army and for conducting combat operations at the beginning of a German war on two fronts, against France and Russia. The plan was formulated in a memorandum compiled in 1905 by the chief of the General Staff, General A. von Schlieffen.

In implementing the plan, the first strike was to be delivered against France by the bulk of the German troops, up to 85 percent of all ground forces. The main forces were to be concentrated on the right flank and moved through neutral Belgium and Luxembourg to outflank the main forces of the French Army from the north, with the objective of seizing Paris and driving French forces back to the east, where they would be surrounded and wiped out. Against Russia, only a weak screening force would be in place, awaiting the victory over France. After France was crushed, the plan envisioned shifting large forces to the war against Russia.

The Schlieffen plan was risky and unprincipled because the German Army in the west did not have superiority in forces and was unable to provide logistic support for a rapid, continuous advance to great depth. The objective of wiping out the French Army of several million in one blow was also unrealistic. When the Schlieffen plan, in somewhat modified form, was put into effect at the beginning of World War I, the German forces were defeated in the battle of the Marne of 1914.

SCHLIEMANN, HEINRICH. Born Jan. 6, 1822, in Neubukow; died Dec. 26, 1890, in Naples. German archaeologist.

Schliemann, who had amassed a vast fortune through trade, retired from business in 1863 and devoted himself to searching for the sites of places mentioned in the Homeric epics. In 1869 he suggested that the site of Troy was the mound of Hissarlik in Asia Minor. Excavations in 1870–73, 1878–79, 1882–83, and 1889–90 confirmed Schliemann's hypothesis and proved that Homer's epic had a sound, factual basis. Schliemann also carried out excavations in Mycenae (1876), on the island of Ithaca (1878), in Orchomenos (1880–81), and in Tiryns (1884–85). Largely self-taught, Schliemann made use of completely unorthodox methodology in his excavations and, despite the fact that he kept detailed diaries and published the results of his excavations, the scientific value of his works is not very great. Of particular importance, however, was Schliemann's discovery of the "pre-Homeric" Aegean culture, studied scientifically by A. Evans after Schliemann's death.

SCHLIERE, a segment of irregularly shaped intrusive rock that differs from the rest of the rock mass by the quantitative proportions of its constituent minerals or by structure. Gradual transitions are usually observed between schlieren and the rock within which they are enclosed. Schlieren are usually 2–10 cm in size, sometimes reaching as much as 1 m and more. Some schlieren are formed when fragments of foreign rock (xenoliths) are invaded and reworked by a magmatic melt. In many cases, such schlieren show continuous transitions from xenoliths that differ greatly from the actual magmatic rock. Sometimes schlieren are accumulations of minerals, frequently ore minerals, that have separated out from the magmetic melt in the early stages of crystallization. [29–1290–4]

SCHLIEREN METHOD, a technique that detects optical inhomogeneities in transparent refractive media and defects of reflecting surfaces.

The schlieren method is used to detect striae in optically transparent materials and to determine the quality of mirrors and other optical parts. It is used to study the density gradients of air flows around wind tunnel models and to project images onto screens (the images are obtained in the form of optical inhomogeneities); it is also used in bubble chambers, large-screen television systems, systems used to reproduce images from thermoplastic and vesicular photographic materials, and other devices. The schlieren method was proposed by the German scientist A. Töpler in 1867.

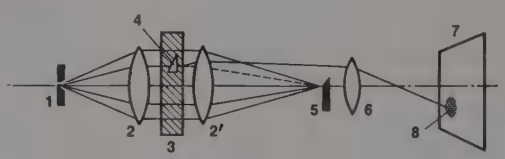

Figure 1

In the schlieren method, a beam of rays from a point or slit source of light (Figure 1) is directed through the object being studied (3) by a lens or a system of lenses and mirrors (2–2′) and is focused on an opaque screen (5) with a sharp edge (a Foucault knife-edge) such that the image of the source is projected on the very edge of the screen. If the object in question has no optical inhomogeneities, all the rays are stopped by the screen. If an optical inhomogeneity (4) is present, the rays will be scattered by the inhomogeneity, and some of them, having been deflected, will pass above the edge of the screen. By placing a projection lens (6) behind the screen, it is possible to project these rays onto the screen (7) and to obtain an image (8) of the inhomogeneities that have scattered the rays. Optical inhomogeneities can be viewed directly by the observer through an eyepiece mounted on the device instead of a projection lens.

Optically conjugate gratings (rasters) that overlap the path of the rays when inhomogeneities are present in their path are sometimes used instead of a point source of light and a Foucault

knife-edge. Gratings with slits in the form of light filters are also used. These make it possible to determine more graphically the character of the optical inhomogeneities. A cruder (shadow) pattern of the zones of abrupt change in the optical density of an object can be obtained if the rays are overlapped by a Foucault knife-edge or gratings. Illumination of the object by two optical systems mounted at an angle to one another makes it possible to obtain a stereoscopic pattern of the distribution of the object's inhomogeneities.

N. A. VALIUS [29–1291–1]

SCHLIPPENBACH, VOLMAR ANTON VON. Born 1650; died 1739. Swedish general.

The son of a Livonian noble, Schlippenbach commanded the Swedish troops in Livland at the beginning of the Northern War of 1700–21. In 1701 and 1702 he was defeated at Erestfehr and Hummelshof and near Dorpat (Tartu). In 1709, in the battle of Poltava, he served under Field Marshal K. G. Rehnschiöld (Rehnsköld), who sent him to aid the detachment of General Roos, which had been checked by Russian redoubts. After Schlippenbach's arrival, the detachment, with Schlippenbach in command, was surrounded and captured by the cavalry units of A. D. Menshikov.

Schlippenbach entered Russian service in 1715 and was promoted to the rank of lieutenant general. He received an estate in Courland and the title of baron. Schlippenbach served as a member of the Military Collegium and, in 1718, as a member of the Supreme Court. [29–1290–3]

SCHLOSSER, FRIEDRICH CHRISTOPH. Born Nov. 17, 1776, in Jever; died Sept. 23, 1861, in Heidelberg. German historian.

Schlosser became a professor at the University of Heidelberg in 1817. His world view developed under the influence of the Enlightenment and of German classical philosophy. Moralistic Enlightenment attitudes dominate his works *The History of the 18th Century* (vols. 1–2, 1823; 5th ed., vols. 1–8, 1864–66; Russian translation by N. G. Chernyshevskii, vols. 1–8, 1858–60) and *World History* (vols. 1–19, 1844–57; Russian translation edited by N. G. Chernyshevskii and V. A. Zaitsev, vols. 1–18, 1861–69). In these works Schlosser opposed the reactionary romantic apologia for the Middle Ages and feudal despotism and defended the ideals of the Enlightenment and the bourgeois revolutions of the 16th to 18th centuries.

Schlosser attempted to produce a history of mankind as a unified whole, with particular attention being paid to the popular masses. His treatment of the democratic movements of the past, however, was not consistent. Schlosser took a generally negative view of the peasant and plebeian movements of the bourgeois revolution in Germany in the 16th century and in France in the 18th century, but he was sympathetic to the Leveler movement in the English revolution of the 17th century. Although he opposed all manifestations of reaction, he remained a supporter of enlightened absolutism, even after the Revolution of 1848–49 in Germany, whose significance in the history of the German people he did not understand. Karl Marx used Schlosser's *World History* as the basis for his *Chronological Extracts* (see *Arkhiv K. Marksa i F. Engel'sa*, vols. 5–8, Moscow, 1938–46).

SCHLÖZER, AUGUST LUDWIG. Born July 5, 1735, in Gaggstadt; died Sept. 9, 1809, in Göttingen. German historian, philologist, and statistician. Adjunct of the St. Petersburg Academy of Sciences (1762). Honorary member of the Society of History and Russian Antiquities (1804).

Schlözer studied at the universities of Wittenberg and Göttingen. At the invitation of G. F. Miller, he worked in Russia from 1761 to 1767 and studied the Old Russian chronicles. As a supporter of the Norman theory of the origin of Rus', he was sharply criticized by M. V. Lomonosov. Schlözer contributed to the publication of V. N. Tatishchev's *History of Russia*. In 1763 and 1764 he composed a grammar of the Russian language. After returning to Germany he taught history and statistics at the University of Göttingen and wrote a number of works on Russian history. His principal work, *Nestor*, had a positive influence on the development of the study of sources in Russia.

A rationalist thinker, Schlözer remained a representative of the moderate trend of the Enlightenment and a supporter of enlightened absolutism. He elaborated concepts of universal history and protested against the division of peoples into "historical" and "nonhistorical."

Schlözer became a foreign honorary member of the St. Petersburg Academy of Sciences in 1769.

SCHLÜTER, ANDREAS. Born circa 1660 in Gdańsk(?); died before June 23, 1714, in St. Petersburg. German sculptor and architect; outstanding representative of the baroque style in Germany.

Schlüter worked from 1689 to 1693 in Warsaw and from 1694 in Berlin, where he was director of the Academy of Arts from 1702 to 1704. In 1696 he sculpted tragically expressive heads of dying warriors on the keystones in the courtyard of the Berlin Arsenal. Striking characterization and dynamic, monumental composition are typical of the equestrian statue of Frederick William, the great elector, on the Lange Brücke in Berlin (bronze, 1696–1703, completed 1709), which is now in the forecourt of Charlottenburg Palace.

From 1698 to 1706, Schlüter directed the reconstruction of the Royal Palace in Berlin, where he built the inner courtyard in the baroque style and designed magnificent interiors. He also completed a portrait bust of Landgrave Frederick II of Giessen and Homburg (bronze, c. 1704, castle courtyard, Homburg) and a number of decorative works. From 1711 to 1712 he built the Villa Kamecke in Berlin.

In 1713, Peter I invited Schlüter to St. Petersburg, where he completed the Summer Palace (1713–14) and designed the Mon Plaisir Palace and grottoes in Petergof (now Petrodvorets).

SCHLÜTER, HERMANN. Born Oct. 8, 1851, in what is now Schleswig-Holstein; died Jan. 26, 1919, in New York. Historian; figure in the working-class movement in Germany and the USA.

Schlüter was involved in the socialist movement from his youth, when he became affiliated with the left wing of German Social Democracy. In the 1870's and 1880's he helped publish a number of newspapers and magazines of the Social Democratic Party of Germany. Schlüter emigrated to the USA in 1889. He contributed to the newspaper *New Yorker Volkszeitung*, and in the early 1890's he became a member of the editorial board of the newspaper. In 1904 he represented the Socialist Party of the USA at the congress of the Second International in Amsterdam. He opposed opportunism in the German and international working-class movement.

Schlüter's historical works, which are devoted primarily to var-

ious aspects of the working-class and democratic movement in the USA, criticize the attempts of bourgeois and social-reformist historiography to reduce the history of the working-class movement in the USA to the trade-unionist struggle. Schlüter is also the author of *The Chartist Movement* (1916; Russian translation, 1925), which contains an objective analysis of Chartism.

SCHMALENBACH, EUGEN. Born Aug. 20, 1873, in Schmalenbach, near Halver, Westphalia; died Feb. 20, 1955, in Cologne. German economist.

In 1906, Schmalenbach became a professor at the University of Cologne. In such works as *Financing* (1915) and *Dynamic Balance* (1919) he examined questions pertaining chiefly to the theory of balanced accounts and the financing of capitalist enterprises. Elevating the capitalists' notions about their day-to-day activities to the status of theoretical concepts, he created a "science of enterprises," which systematized rules for the most profitable management of the economy. Writing as a defender of monopoly capital, he outlined paths for the improvement of accounting, techniques of commerce, commodity circulation, and credit as means of increasing profits and overcoming the contradictions of the capitalist mode of production. An ideologist of "organized" capitalism, Schmalenbach advocated the organization of the economy into trusts with the help of the state. [29–1309–3]

SCHMALKALDEN, a city in the German Democratic Republic, in Suhl District. Population, 15,000 (1975). Schmalkalden has traditionally been a producer of small metal articles; machine tools are also manufactured in the city. [29–1310–2]

SCHMALKALDIC LEAGUE, a political alliance of German Protestants formed in response to Emperor Charles V's refusal to acknowledge the Augsburg Confession. The league was established on Feb. 27, 1531, in the Thuringian city of Schmalkalden. Its members included such Lutheran princes as elector John Frederick of Saxony, Landgrave Philip of Hesse, and, later, Ulrich of Württemberg and Duke Maurice of Saxony, as well as such cities as Magdeburg, Bremen, Strasbourg, and Ulm. In the Schmalkaldic War (1546–48) the league was defeated by Charles V and disbanded. [29–1311–2]

SCHMALKALDIC WAR (1546–48), a war between the emperor of the Holy Roman Empire, Charles V, who was attempting to restore Catholicism in Germany, and the Protestant Schmalkaldic League.

The negotiation of a peace treaty with France in 1544, the conclusion of a truce with the Ottoman Empire in 1545, and the defection of Duke Maurice of Saxony to the side of the emperor enabled Charles V to begin the war in July 1546. Additional troops from the Netherlands and the pope gave the emperor a substantial military advantage. In late 1546, Maurice seized the lands of his relative Elector John Frederick of Saxony. The Protestant troops were routed at Mühlberg, Saxony, on Apr. 24, 1547, and John Frederick, who had been taken prisoner, renounced his electorate in favor of Maurice. On June 19, 1547, another Protestant leader, Philip of Hesse, surrendered.

Fighting resumed in 1552 with a revolt of the Protestant princes. The new war ended in a victory for the princes that was given official recognition by the Treaty of Passau (1552) and the religious Peace of Augsburg (1555). [29–1311–1]

SCHMIDT, ADOLF. Born July 23, 1860, in Breslau (now Wrocław); died Oct. 17, 1944, in Gotha. German geophysicist.

Schmidt graduated from the university in Breslau in 1882. He became director of the magnetic observatory in Potsdam in 1902 and of the magnetic-meteorological observatory in 1909. He was named an honorary professor of the University of Berlin in 1907. Schmidt's principal works dealt with the theory of geomagnetism, magnetic surveys, and the study of geomagnetic variations. In 1915–16, Schmidt constructed vertical and horizontal field magnetic scales.

SCHMIDT, HELMUT. Born Dec. 23, 1918, in Hamburg. Statesman of the Federal Republic of Germany.

Schmidt graduated with a degree in political economy from the University of Hamburg in 1949. In 1946 he had joined the Social Democratic Party of Germany (SDPG). Schmidt served as a deputy to the Bundestag from 1953 to 1962 and was elected again in 1965. He was chairman of the Social Democratic faction in the Bundestag from 1967 to 1969; he had become vice chairman of the SDPG in 1968. In a coalition government formed by the SDPG and the Free Democratic Party, Schmidt held the posts of minister of defense (1969–72), minister of economics and finance (1972), and minister of finance (1972–74). Schmidt became federal chancellor in May 1974. [29–1317–2]

SCHMIDT, ISAAC JAKOB (also Iakov Ivanovich Shmidt). Born Oct. 14 (25), 1779, in Amsterdam; died Sept. 8 (20), 1847, in St. Petersburg. Russian linguist. Academician of the St. Petersburg Academy of Sciences (1829).

Schmidt's main works dealt with the Mongolian and Tibetan languages. He was the author of the first grammar of the Mongolian language (1831), a grammar of the Tibetan language (1839), and a number of dictionaries. He translated the Mongolian epic *The Exploits of Bogdy Geser Khan* (1836; German translation, 1839) into Russian. Schmidt published, in German translation, the *Mongolian Chronicles of Sagan Setsen, 1662* (1829) and the Tibetan work *Uligerun-Dalai* (1843). The latter was the first Tibetan book translated into a European language.

SCHMIDT, JOHANNES. Born July 29, 1843, in Prenzlau; died July 4, 1901, in Berlin. German linguist.

Schmidt studied Indo-European languages at the universities of Berlin and Jena. He became a professor at the University of Graz in 1873 and at the University of Berlin in 1876. He was a specialist in comparative Indo-European linguistics. In place of A. Schleicher's family tree model of the development of the Indo-European language family, Schmidt proposed the wave theory to account for the distribution of the Indo-European languages. According to this theory, Proto-Indo-European, while still united as a family of dialects, constituted an aggregate of linguistic innovations, which radiated like waves from the center of the linguistic unity toward its periphery. The Indo-European languages, according to Schmidt, are connected by a number of common features; they lack well-defined boundaries, and there are gradual and imperceptible transitions from one language to another.

Schmidt's works had a considerable influence on the development of Indo-European dialectology. Schmidt became a foreign corresponding member of the St. Petersburg Academy of Sciences in 1892.

SCHMIDT, WILHELM. Born Feb. 16, 1868, in Hörde; died Feb. 10, 1954, in Fribourg, Switzerland. Austrian ethnologist and linguist; head of the Vienna school of cultural history. Catholic priest.

Schmidt was a professor at the University of Vienna from 1921 to 1938 and became a professor at the University of Fribourg in 1939. He was a specialist in the languages of Southeast Asia, Oceania, and Australia and their comparative study and classification. In his work *The Origin of the Idea of God* (vols. 1–12, 1912–52), he used his vast ethnological erudition to substantiate the theological theory of primitive divine revelation and the consequent theory of primeval monotheism.

Despite the erroneousness of his main views, the extensive material that Schmidt collected on primitive beliefs and especially on languages has considerable scholarly value. In 1906, Schmidt founded the journal *Anthropos*; initially containing ethnological reports by missionaries of his order, it later became an international scholarly organ.

SCHMIDT, WILHELM MATTHÄUS. Born Jan. 21, 1883, in Vienna; died there Nov. 27, 1936. Austrian geophysicist.

After graduating from the University of Vienna in 1905, Schmidt worked at the Central Institute for Meteorology and Geodynamics in Vienna. In 1912 he became a teacher at the Higher School of Soil Science in Vienna, where he became a professor in 1919. Beginning in 1930, he was a professor and director of the meteorological observatory of the University of Vienna.

Schmidt studied the turbulent mixing of the lower layers of the atmosphere and lake waters and introduced the concept of the coefficient of mixing.

SCHMIDT CORRECTION PLATE, an optical part of the Schmidt telescope designed to compensate for spherical aberration in the telescope's primary mirror, which has a spherical shape. The Schmidt correction plate, which is mounted at the center of curvature of the primary mirror, is a glass plate one surface of which is flat and the other surface of which has a complex form described by the equation

$$x = (y^4 - ay^2)A^3D/512(n - 1)$$

where A is the relative aperture, D is the diameter of the primary mirror, n is the index of refraction of the plate material, and a is a free parameter on the selection of which the chromatism of the plate depends (minimum chromatism is achieved when $a = 1.5$).

The Schmidt correction plate introduces in the optical system a spherical aberration equal in magnitude but opposite in sign to the spherical aberration of the primary mirror, thus making the system stigmatic. N. N. MIKHEL'SON [29–1321–2]

SCHMIDT NUMBER 1, a similarity criterion of the motions of liquids or gases in which processes of internal friction and diffusion are significant.

The Schmidt number 1, the diffusion analog of the Prandtl number, is the ratio of the kinematic viscosity coefficient ν of the liquid or gas to the diffusivity D. The Schmidt number 1 is $N_{Sc} = \nu/D$, where $\nu = \mu/\rho$ (μ is the viscosity coefficient and ρ is the density). The Schmidt number 1 characterizes the relative role of molecular processes of the momentum and mass transfer of an impurity by diffusion. In ideal gases, $N_{Sc} = 1$, since $\upsilon = D$; in real gases it may differ from 1.

The Schmidt number 1 is named in honor of W. M. Schmidt. It is often called the Prandtl diffusion number, which is designated Pr_D. [29–1323–1]

SCHMIDT TELESCOPE, an astronomical mirror-lens telescope designed for photographing large areas of the sky. The Schmidt telescope was invented in 1929 by the German opticist B. Schmidt. Its main components are a spherical mirror and a Schmidt correction plate, which is mounted at the center of curvature of the mirror (see Figure 1). As a result of the placement of the correction plate, all beams of rays passing through it from different parts of the sky prove to be equally corrected with respect to the mirror. Consequently, the Schmidt telescope lacks such aberrations of optical systems as coma, astigmatism, and distortion.

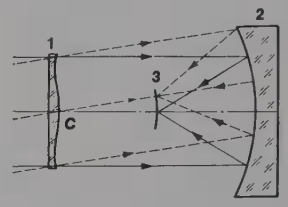

Figure 1. Optical scheme of a Schmidt telescope: (1) correction plate, (2) concave spherical mirror, (3) convex focal surface, (*C*) common center of the mirror and focal plane

The spherical aberration of the mirror is corrected by the correction plate, the central part of which acts as a weak positive lens, and the outer part, as a weak negative lens. The focal surface, on which the image of a segment of the sky is formed, has a spherical shape, whose radius of curvature is equal to the focal distance of the telescope. The focal surface can be converted into a flat surface by means of a Piazzi-Smyth lens. In small Schmidt telescopes, the field of view is limited by a cassette that screens the beam of rays incident on the mirror; in large Schmidt telescopes, it is limited by the aberrations of oblique rays, which are introduced by the correction plate. This plate, in correcting spherical aberrations, gives rise to small residual aberrations (coma and astigmatism), which spoil the image. The chromatism of the correction plate limits the relative aperture of Schmidt telescopes and the operating region of the spectrum. A Schmidt telescope with a primary mirror of a small diameter at a relative aperture $A = 1{:}1$ provides a field of view 20° in diameter; at larger diameters of the primary mirror and at A from 1:2 to 1:3, the diameter of the field of view is about 5°. To eliminate vignetting of the rays at the edge of the field, the diameter of the primary mirror must exceed the diameter of the correction plate by $4l$, where $2l$ is the diameter of the field of view in linear measurement.

A shortcoming of Schmidt telescopes is the considerable length of the tube, which is twice the focal length of the telescope. A number of modifications, including the use of a second (supplementary) convex mirror and the placement of the correction plate closer to the primary mirror, have been proposed to eliminate this shortcoming.

The largest Schmidt telescopes are mounted at the astronomical observatory in Tautenberg in the German Democratic Republic ($D = 1.37$ m, $A = 1{:}3$), the Mount Palomar Observatory in the United States ($D = 1.22$ m, $A = 1{:}2.5$), and the Biurakan Astrophysical Observatory of the Academy of Sciences of the Armenian SSR ($D = 1.00$ m, $A = 1{:}2, 1{:}3$).

SCHMITT, HARRISON HAGAN. Born July 3, 1935, in Santa Rita, N.M. US astronaut.

Schmitt graduated from the California Institute of Technology in 1957 with a B.S. in geology. He studied at the University of Oslo in 1957 and 1958 and received a Ph.D. in geology from Harvard University in 1964. Schmitt worked in Oslo for the Norwegian Geological Survey, in New Mexico and Montana for the US Geological Survey, and in Alaska for two summers as a geologist for a private concern.

Schmitt became a member of the National Aeronautics and Space Administration astronaut corps in 1965. Immediately before his association with the Manned Spacecraft Center, he worked at the Astrogeological Center of the US Geological Survey in Arizona, where he helped compile maps of the moon and the planets. From Dec. 7 to Dec. 19, 1972, as pilot of the Apollo 17 lunar landing module, Schmitt made a flight to the moon with E. Cernan and R. Evans. With Schmitt and Cernan aboard, the lunar module touched down in the Taurus-Littrow Valley on December 11. Schmitt's 75 hr on the moon included three excursions onto the surface, for a total of 22 hr 5 min of extravehicular activity. Schmitt and Cernan used what was called a lunar rover to move about on the moon. The entire flight lasted 12 days 9 hr 51 min. [29–1323–3]

SCHMOLLER, GUSTAV VON. Born June 24, 1838, in Heilbronn; died June 27, 1917, in Bad Harzburg. German economist, historian, and state and public figure.

A leading representative of the new (younger) historical school of political economy, Schmoller became a professor at the University of Halle in 1864, the University of Strassburg in 1872, and the University of Berlin in 1882. He became a member of the Prussian Staatsrat (State Council) in 1884 and the Prussian Herrenhaus (Upper House) in 1899. He helped found the Verein für Sozialpolitik (Association for Social Policy) in 1872 and became its chairman in 1890. In 1881 he assumed the editorship of the *Jahrbuch für Gesetzgebung, Verwaltung und Volkswirtschaft im deutschen Reich*.

Schmoller's principal theoretical work was *Foundations for the Comprehensive Study of National Economy* (vols. 1–2, 1900–04). Basing his theories on the ideas of the historical school, he criticized the formal deductive constructs of classical political economy. According to Schmoller, concrete historical research must precede the creation of an economic theory, since only a historical approach makes it possible to determine the causal relations between social phenomena. The behavior of economic entities (individuals and groups) results from the interaction of a variety of factors; therefore, economic science should concern itself with, for example, the intentions of individuals considered as economic units, the level of technological development, the character of existing social institutions, and natural conditions. Schmoller suggested that political economy, as the basic social science, encompasses such disciplines as psychology, sociology, and geography; it is therefore normative and provides a basis upon which to make ethical judgments and practical recommendations.

Criticizing Marxism from the perspective of Katheder-socialism, Schmoller defended active government intervention in the economy in order to stimulate the national economy and mitigate class contradictions. The existence of social classes—whose emergence he linked with racial characteristics, the division of labor, and unequal distribution of income—and the struggle between social classes were considered a necessary condition for social progress. He saw the aim of class struggle, however, not as the revolutionary transformation of society but as a compromise between the opposing parties, who must not violate common ethical standards. Schmoller wrote several works on the socioeconomic and political history of various countries of Western Europe.

L. D. GUDKOV [29–1324–1]

SCHNEEBERG, a city in the German Democratic Republic, in Karl-Marx-Stadt District. Population, 20,800 (1975). Schneeberg has a textile industry. Other industries include nonferrous metallurgy, engine building, and the manufacture of leather, toys, and lace. The city is known for its wood carving. [29–1326–1]

SCHNEIDER, one of the oldest groups of monopoly capital in France. A major role in the group, which emerged in the first half of the 19th century, is played by the Schneider family.

In 1836, Eugène Schneider and his brother Adolphe acquired metallurgical and metalworking plants in the city of Le Creusot; these developed into the large weapons and metallurgical concern Schneider-Creusot. After World War I the concern controlled enterprises and companies of the machine-building, shipbuilding, automobile, and power-engineering industries, as well as several large French financial institutions.

In 1936, when the nationalization of the French weapons industry went into effect, the plants of Schneider-Creusot devoted solely to arms manufacture were bought by the government. After World War II the government took similar measures with regard to the concern's coal and power-engineering enterprises, insurance business, and several of its banks. In order to build itself up again and modernize production, the concern made extensive use of government aid and accepted approximately $2 million in American credit under the Marshall Plan. In the years after this rebuilding program, the two leading companies in the group were Schneider et Cie and the Union Europeene Industrielle et Financière, which controlled the Schneider industrial and financial empire. The Schneider group is a typical example of a modern trust: a large number of companies, legally independent, are controlled by the holding company Schneider et Cie, which works in concert with the banks and other financial institutions in the group.

In the late 1960's and early 1970's the competitive struggle among the financial groups within the country intensified, and American and Western European corporations increasingly were able to establish themselves in the French economy; during this period Schneider was taken over by the more powerful Empain group, within which it continues to play a major role in the areas of ferrous metallurgy, machine building, and banking. As one of the government's military contractors, the Schneider group manufactures artillery pieces, tanks, and instruments and forms part of the military-industrial complex. The Schneider group has extensive interests in the Federal Republic of Germany, Belgium, and Luxembourg.

SCHNEIDERHÖHN, HANS. Born June 2, 1887, in Mainz; died Aug. 5, 1962, in Sölden, near Freiburg, Federal Republic of Germany. German geologist.

After graduating from the Justus Liebig University in Giessen in 1909, Schneiderhöhn worked as an assistant at the University of Berlin from 1909 to 1914. From 1914 to 1919 he conducted a study of the regional geology and ore deposits of southwestern Africa. Beginning in 1920, he was a professor at the Justus Liebig University. In 1924 he was named director of the Mineralogical Institute of the Technische Hochschule in Aachen. From 1926 to

1955 he was a professor and director of the Geological Institute of the Albert Ludwig University in Freiburg.

Schneiderhöhn's principal works dealt with the development of optical methods of studying ores using a polarizing microscope in beams of reflected light and with the investigation of the origin of ore deposits. Schneiderhöhn substantiated the sedimentary origin of ores in the cuprous sandstones of Africa, the volcanic-sedimentary origin of the copper pyrite deposits of Germany, and the regenerative origin of the ore deposits of the Alpide and Pacific geosynclinal belts. He was the author of well-known textbooks on the geology of ore deposits (1931, 1941).

Schneiderhöhn was a member of scientific societies and academies of sciences of various countries.

SCHNITZLER, ARTHUR. Born May 15, 1862, in Vienna; died there Oct. 21, 1931. Austrian writer.

Schnitzler graduated from the medical faculty at the University of Vienna in 1885. His best works written in the late 19th and early 20th centuries continue the traditions of critical realism; they expose the hollowness and cruelty of the worldly life and defend the primacy of true feeling. In the drama *Free Game* (1896; Russian translation under the title *A Slap in the Face*, 1897) and the short story "Lieutenant Gustl" (1901), he portrayed the amorality and the caste-conscious arrogance of officers in the Austrian Army. The effect of Schnitzler's critical statements was weakened, however, by his use of decadent motifs: his play *The Green Cockatoo* (1899) was concerned with the illusoriness of life, and his series of one-act plays *Paracelsus* (1899) dealt with the cult of eternal beauty.

Schnitzler's prose, which includes the novella *Casanova's Homecoming* (1918) and the short-story collections *The Sage's Wife* (1898) and *Masks and Miracles* (1912), is distinguished by psychological insight and an intense concern with sex. Schnitzler was influenced by S. Freud; Freudian tendencies are especially apparent in such late works as the novella *Theresa* (1928).

SCHÖFFEN, in medieval Germany, the members of the juridical collegium that determined punishments jointly with the judge presiding over a trial. The institution of the *Schöffen* was based on the Frankish college of *scabini*. The word later came to designate jurors with various powers. [29–1167–3]

SCHOMBURGK, ROBERT HERMANN. Born June 5, 1804, in Freyburg an der Unstrut; died Mar. 11, 1865 in Schöneberg, near Berlin. German explorer in the service of Great Britain.

From 1835 to 1839 and from 1840 to 1844, Schomburgk explored British Guiana (now the Republic of Guyana) and adjacent territories with his brother Richard, a botanist. He mapped the basin of the Essequibo River, discovered the Pakaraima and Roraima mountains, and explored the upper course of the Rio Branco and the upper course and delta of the Orinoco River. In 1860, Schomburgk traveled to Thailand, where he assembled rich zoological and botanical collections.

SCHÖNBEIN, CHRISTIAN FRIEDRICH. Born Oct. 18, 1799, in Metzingen, in what is now the *Land* (state) of Baden-Württemberg in the Federal Republic of Germany; died Aug. 29, 1868, near Baden-Baden. German chemist.

Schönbein studied at the universities of Tübingen and Erlangen. He taught in Switzerland and became a professor at the University of Basel in 1828. He discovered ozone in 1840. Schönbein obtained pyroxylin in 1845, and in 1846 he became the first to prepare collodion from it. [29–1124–2]

SCHÖNBERG, ARNOLD. Born Sept. 13, 1874, in Vienna; died July 13, 1951, in Los Angeles, Calif. Austrian composer.

From 1901 to 1903, Schönberg taught composition at the Stern Conservatory in Berlin. In 1903 he moved to Vienna, where he became known as a composer, conductor, and teacher and as an organizer and director of choral groups. He was a professor at the Prussian Academy of Arts in Berlin from 1925 to 1933. After the fascists came to power, he was forced to emigrate to the USA, where from 1936 to 1944 he taught composition at the University of California at Los Angeles.

In his early works, most notably in the string sextet *Verklärte Nacht* (Transfigured Night; 1899) and the symphonic poem *Pelleas und Melisande* (1903), Schönberg continued the traditions of German and Austrian romanticism and of R. Wagner. Later he developed the dodecaphonic, or twelve-tone, system of composition. Schönberg was the founder of atonal music and the most prominent representative of musical expressionism. His theories greatly influenced several generations of composers, notably—in addition to such students and followers of his as A. Berg and A. von Webern—E. Wellesz, E. Křenek, and R. Leibowitz.

Schönberg most consistently applied the twelve-tone system in such works as the *Fünf Klavierstücke* (1923), the *Serenade for Septet and Baritone* (1923), the concerti for violin (1936) and piano (1942), the monodrama *Erwartung* (1909, staged 1924), and the opera *Moses und Aron* (1932; concert performance, 1954). The music of these works, marked by artificiality and expressionist angst, is devoid of melody.

Shaken by the fascists' destruction of the Warsaw ghetto, Schönberg wrote the story for speaker with orchestra and male chorus *A Survivor From Warsaw* (1947), in which he departed from his characteristic subjectivism. In his works Schönberg protested against the inhuman laws of the bourgeois state, but his overriding theme remained the tragic isolation of the artist in an alien and hostile world.

In addition to *Pierrot Lunaire* (1912), written for voice with chamber accompaniment, Schönberg's other principal works include two chamber symphonies (1906 and 1939), four string quartets, compositions for voice and for piano, and numerous theoretical works.

SCHÖNBRUNN, TREATY OF (1805), a treaty between France and Prussia. It was signed on Dec. 15, 1805, in the Schönbrunn Palace in Vienna by General M. Duroc for the French side and Minister C. von Haugwitz for the Prussian side.

The signing of the Treaty of Schönbrunn signified Prussia's virtual renunciation of the provisions of the Potsdam Alliance Convention of 1805 between Prussia and Russia. The treaty required Prussia to cede some of its territories to France, including Neuchâtel, Ansbach, and Kleve; in return it received Hanover, which the French had taken from Great Britain in a calculated attempt by Napoleon to drive a wedge between Prussia and Great Britain. The treaty was not ratified by the Prussians, but its principal terms were incorporated into the Treaty of Paris of 1806, which was signed by Prussia and France on February 15.

SCHÖNBRUNN, TREATY OF (1809) (also Schönbrunn Peace), a treaty between France and Austria signed on Oct. 14, 1809, at the Schönbrunn Palace in Vienna, after the conclusion of the Austro-French War (Austrian War of Liberation) of 1809.

Austria was forced to cede Salzburg to Napoleon I for transfer to Bavaria; the county of Görz (Gorizia), Istria, Trieste, Carniola, Fiume (Rijeka), and parts of Carinthia and Croatia passed from Austria directly to France and were included in Napoleon's Illyrian Provinces. Western Galicia was ceded by Austria to the Grand Duchy of Warsaw; the Tarnopol' district of Galicia passed from Austria to Russia as compensation for Russia's participation in the war on the side of the French.

Austria was obligated to join the continental blockade, to break off relations with Great Britain, and to recognize all changes to be carried out by Napoleon in Spain, Portugal, and the Italian states; the treaty specifically stipulated that Austria must renounce intervention in the internal affairs of these states. The strength of the Austrian army was reduced to 150,000 men, and a large indemnity was imposed on Austria. The integrity of the remaining Austrian possessions was guaranteed by Napoleon.

The treaty, which transformed Austria into a virtual dependency of France, was annulled by the Congress of Vienna of 1814–15.

SCHÖNEBECK, a city in the German Democratic Republic, in Magdeburg District, on the Elbe River. Population, 45,000 (1975). Schönebeck is a railroad junction and river port. Industry includes the manufacture of tractors, diesel engines, chemicals, and rubber and concrete products. Bad Salzelmen, a health resort with salt springs, is located near Schönebeck. [29–1128–2]

SCHONGAUER, MARTIN (also Schön Martin). Born between 1435 and 1440 in Colmar, now in France; died Feb. 2, 1491, in Breisach, Baden. German graphic artist and painter.

Schongauer studied in the Netherlands, where he was greatly influenced by Rogier van der Weyden. Schongauer worked in Colmar and Breisach beginning in 1483. He is known for his paintings, including *Madonna in a Rose Garden* (1473), and especially for his copper etchings, such as *The Temptation of Saint Anthony, The Annunciation, Calvary, Madonna in a Courtyard, Peasants Going to Market*, and a series of passion scenes. These works are distinguished by expressiveness of form, and several are examples of harmonious, clear composition. Schongauer's works combine features of the late Gothic and the early Renaissance. They had a significant influence on the masters of the German Renaissance, including A. Dürer.

SCHÖNGRABERN, BATTLE OF (1805), a battle fought between Russian and French troops on November 4 (16), near the village of Schöngrabern, Austria, near Hollabrunn, during the Russo-Austro-French War of 1805 (War of the Third Coalition).

With Vienna occupied by the French, the Russian Army, commanded by M. I. Kutuzov, found itself in a difficult position as it retreated to Znaim (Znojmo) after crossing the Danube at Krems. Kutuzov sent General P. I. Bagration's detachment of 6,000 men to Schöngrabern to delay the advance of the French marshal J. Murat's vanguard of 30,000 men, which was moving toward Znaim to cut off the Russian Army's line of retreat. Owing to skillful leadership and the tenacity of his troops, Bagration, in stubborn fighting in which the Russians lost more than 2,000 men, succeeded in delaying the enemy and protecting the withdrawal of the main forces. Bagration's detachment then retreated and on November 6 (18) joined the main forces at Pohrlitz (Pohořelice). [29–1127–3]

SCHÖNHERR, KARL. Born Feb. 24, 1867, in Axams, Tirol; died Mar. 15, 1943, in Vienna. Austrian dramatist and prose writer.

Schönherr studied medicine and philosophy at the University of Vienna. At the beginning of the century, influenced by the traditions of the realistic drama of L. Anzengruber, he wrote plays that were critical of village life, including the comedy *Earth* (1907). Schönherr heroized and romanticized rural life to a certain extent and introduced a demonic element in such plays as *A Tirolean Judas* (1927) and *A People in Need* (1916). The consequent attempts of the ideologists of "blood and soil" to use Schönherr's name and works for profascist purposes provoked a strong protest from the writer. He voiced criticism of Hitler after 1933 and vehemently opposed the Austrian *Anschluss*.

Schönherr was also the author of the tragedy *Faith and Fatherland* (1910), of psychological dramas, and of humorous prose written in the Tirolean dialect.

SCHÖNHERZ, ZOLTÁN. Born July 25, 1905, in Košice, Czechoslovakia; died Oct. 9, 1942, in Budapest. Figure in the Czechoslovak, Hungarian, and international working-class movements; an electrical engineer by education.

After graduating from Charles University in Prague, Schönherz worked for the Communist Party of Czechoslovakia (CPC). In 1934 he served as secretary of the Hungarian group of the Youth League of Slovakia; in 1935 he was a representative of the Czechoslovak Communist Youth in the Communist International of Youth. Schönherz helped organize an antifascist league of Slovak and Hungarian youth organizations between 1936 and 1938, and he was one of the leaders of the Hungarian Youth League, which was established by the CPC. In December 1940 he became a member of the Secretariat of the Communist Party of Hungary (CPH), and in January 1941 he became a member of the Central Committee. As a participant in the resistance movement in Hungary, he headed the Committee for National Independence and contributed to the newspaper *Szabad nép*, an organ of the CPH.

Schönherz was arrested on July 6, 1942, and was executed in accordance with the sentence of a military tribunal.

SCHOOL, in art, a trend represented by a group of students and followers of some artist, for example, the Venetsianov school, or by a group of artists who share similar creative principles and work in a similar style, such as the Stroganov school of icon painting. The term is also applied to the painting and sculpture of a city or region when the works in question date from a specific period and are stylistically distinguishable as a group, for example, the Bolognese school. The term may be extended to refer to the art of an entire country, for example, the Flemish school.

[29–1262–1]

SCHOOL, an institution for the organized education, instruction, and upbringing of the rising generation, as well as adults and young workers.

Schools may be classified according to who organizes them and where they get their funds as state, municipal (local-government), or private; private schools are supported by social or religious organizations or by private individuals. Depending on their course of instruction, schools may be classified as general or vocational (specialized); the level of education offered may be primary, incomplete secondary, secondary, or higher. With respect to religion, schools may be secular or sectarian. They may be classified according to the students' sex as boys' (men's), girls' (women's), or coeducational. The aims, tasks, and nature of schools depend on the society's level of development and its class structure.

The first schools originated in the countries and states of the ancient East, such as Babylonia, Assyria, Egypt, and India. They included temple schools for priests, palace schools for the education of the aristocracy, and schools for scribes, who were needed in administrative and economic management. In the classical world, the school was a highly important part of the Spartan, Athenian, and Roman systems of upbringing (*see* SPARTAN UPBRINGING; GREECE, ANCIENT: Education; and ROME, ANCIENT: Education).

In the feudal period, schools in the East developed under the influence of the dominant religions—Hinduism, Buddhism, and Islam—and served the interests of the feudal lords. In India, for example, schools were attached to large temples and were intended mainly for the children of Brahmans and Kshatriyas. In addition to reading and writing, instruction was given in the sacred books, epic poems, mythology, grammar, literature, history, philosophy, mathematics, astronomy, and medicine. The children of the lesser landowners were taught reading, writing, and arithmetic in their local language at "communal" Hindu schools attached to rural temples. At Buddhist monasteries in the East there were, in addition to primary and secondary schools, higher theological schools, at which religious subjects and such sciences as mathematics and astronomy were taught. In Muslim regions and countries there were *maktabs* (Muslim primary schools) and madrasas (Muslim secondary and higher schools).

In medieval Western Europe the Catholic Church established a monopoly over education, and all schools came under the control and ideological direction of the church. Beginning in the fifth century, elementary parish schools for boys were created at some churches, monastic schools were established at monasteries, and bishop's schools, also known as cathedral or episcopal schools, were founded in episcopal sees. The growth of the medieval cities was accompanied, in the 12th century, by the founding of the first universities. In the 13th and 14th centuries, to provide an alternative to the church schools, craft and guild schools were opened, which evolved into municipal schools in the 15th and 16th centuries. As the system of church schools developed, new schools were established for the children of secular feudal lords, such as the aristocratic grammar and public schools in England, the *Ritterakademien* in Germany, and the classical *Gymnasiums* in Germany and other countries (*see* CLASSICAL EDUCATION). The children of the townspeople studied at burgher schools, *Realschulen*, trade schools, and technical schools.

With the rise of capitalism in Western Europe, the social-estate school became the class, bourgeois school, in which, as V. I. Lenin pointed out, "education is organised in one and the same way, and is equally accessible to all the *wealthy*" (*Poln. sobr. soch.*, 5th ed., vol. 2, p. 476). In developed capitalist countries, laws were passed in the 19th century to establish universal compulsory primary education for children of both sexes, and schools were declared uniform and secular. In practice, this legislation was never fully implemented. In addition to classical secondary schools, *Realschulen* and vocational schools continued to be established; these schools met the needs of the bourgeoisie for trained personnel in trade and industry (*see* REALSCHULE EDUCATION). The natural sciences were gradually added to the curricula of the classical schools.

Schools in the colonized countries of Asia, Africa, and Latin America served the interests of the ruling classes of the respective mother countries, notably Spain, Great Britain, and France. The need for auxiliary personnel from the indigenous ("aboriginal") population that would be loyal to the colonialists made it necessary to establish a variety of schools for the "coloreds" with instruction in the language of the mother country. In addition to primary schools, these included a small number of advanced primary schools; secondary schools, such as secondary grammar schools, colleges, *collèges*, and *lycées*; and higher educational institutions, including universities. Instruction was given in the language of the respective mother country.

The institutions established by the colonial powers trained future overseers and civil servants, as well as soldiers and junior officers for the "colored troops." Students included the children of the local aristocracy and bourgeoisie; the sons of tribal chiefs attended closed privileged schools. The rise of national liberation movements hastened the establishment of higher educational institutions; India, for example, had 18 universities before World War II. The schools were, however, strictly controlled by the colonial powers. The bulk of the indigenous population remained illiterate. This harsh legacy of colonialism is being overcome in the countries that have achieved independence.

Before the October Revolution of 1917 the emergence of the first schools and the development of school systems among the peoples who make up the USSR were determined by the particular historical features of the development of these peoples. In Armenia and Georgia, information on the first schools dates from the fourth century and in Azerbaijan from the fifth century. In Middle Asia and Azerbaijan, Muslim *maktabs* and madrasas were established beginning in the seventh century and remained unrivaled until the October Revolution.

The chronicles do not provide a complete picture of schools in Kievan Rus', which were established between the tenth and 13th centuries at monasteries, in parishes, and at the courts of princes. The *beresto* writings of the 11th–15th centuries contain information on the methods used to teach reading and writing, and they show that literacy in ancient Rus' extended to the feudal aristocracy, the clergy, and the townspeople, as well as to the *posadskie liudi* (urban merchants and artisans) and other merchants and artisans.

In prerevolutionary Russia various primary schools existed for the broad masses. The wealthy classes educated their children at *Gymnasiums*, *Realschulen*, commercial schools, and higher educational institutions, including universities. Elements of the system of social estates were preserved in the school system, notably in the restricted educational institutions for the nobility: the cadet corps, the *lycées*, the Corps of Pages, and the institutes for wellborn girls. In addition, the educational system did not provide for a transition from the primary (public) schools to the *Gymnasiums*. Entry into schools was subject to national and religious restrictions.

The church was charged with inculcating loyal sentiments and piety in the youth. In addition to special schools for training the clergy, the Synod directly controlled the system of literacy schools, parochial schools, and eparchial schools. Religion was a compulsory subject in all schools. The level of literacy in Russia lagged behind that in the developed capitalist countries, and illiteracy was prevalent among the working people. Lenin noted in 1913 that "four-fifths of the rising generation are doomed to illiteracy by the feudal state system of Russia" (*ibid.*, vol. 23, p. 127).

Schools in the USSR and other socialist countries. After the October Revolution of 1917, schools were declared public and open to all, irrespective of social status or nationality. Coeducational instruction was introduced in 1918. Schools were separated from

the church and became state controlled and secular. The goal of the schools, as stated in the Program of the RCP(B) of 1919, was to "educate a generation that will be capable of fully establishing communism" and to produce well-rounded and harmoniously developed individuals with firm communist beliefs. The structure, curricula, and organization of Soviet schools undergo changes as socialist society develops and as science and culture advance, but they rest on principles that remain constant.

General-education schools train their students for labor and provide a polytechnical education (*see* SECONDARY GENERAL-EDUCATION SCHOOL and POLYTECHNICAL EDUCATION). In addition to vocational training, specialized secondary educational institutions offer a general education. Instruction is free at all types of schools, and at such institutions as boarding schools and vocational-technical institutions some students are maintained at state expense. Students at specialized secondary educational institutions and higher educational institutions receive government stipends (*see* HIGHER EDUCATION).

The school system is uniform, and the various types of schools represent a continuous series, so that a student may advance from the primary to the highest level. The children of each nationality of the USSR have the right to be taught in their native language. Universal primary education was made compulsory in 1934, and universal eight-year education in 1962. By 1976 the transition to universal secondary education had essentially been completed.

The other socialist countries have looked to the USSR as a model for building an educational system; at the same time, they have taken into account their own specific historical conditions and national characteristics. The socialist countries conform to a common pattern in the construction of a new society and the education of well-rounded individuals capable of becoming builders of socialism and communism. The schools of the socialist countries operate according to uniform principles, although they may be of different types and may have different designations and structures; in addition, the length of instruction and the level of compulsory universal education may vary.

Schools in modern capitalist countries. An aspect of the general crisis of capitalism is the educational crisis in bourgeois countries, which is manifested in their inability to restructure the educational system to meet the needs of industrial development. The bourgeois school system, whose goals remain unchanged, seeks to create for the bourgeoisie "useful servants, able to create profits for it without disturbing it" (Lenin, *ibid.*, vol. 41, p. 303).

State appropriations for education in the capitalist countries are not sufficient to operate a school system in a proper fashion. In several countries, such as Great Britain, the USA, France, the Federal Republic of Germany, and Japan, secondary schools are becoming more widespread, and measures are being taken to reorganize the school system, its curricula and instructional methods, and its management. Existing legislation on universal compulsory education for the poorest strata of the population is not being implemented, however, because of widespread unemployment and racial and national discrimination; equal secondary education is not universally available. Subtle methods for preserving class inequalities, reflected in the material being taught and in the quality of instruction, exist in schools of various types. There are also sophisticated ways of selecting by class the students who will advance to the higher educational levels and who will specialize in prestigious areas of study; this selection is accomplished through the track system, the existence of expensive private schools, and special tests.

(Schools are also discussed in the sections on education and cultural affairs in the articles on Union republics, autonomous republics, and foreign countries.)

SCHOOL ADMINISTRATION (Russian, *shkolovedenie*), the branch of pedagogy that studies the means and methods of administering schools, reveals the distinctive features in the system of school management, and analyzes the specific problems involved in organizing such a system.
